Well that didn't help. It ran all afternoon real solid and then this evening, I had to run the band switch again to get it to stabilize.

Couple of questions.

1. I see most of you are using Deoxit D5. Is that a better option then the D100 I am using?

2. Is this kind of par for the course for the TS-820? Do you just have to run the band switch back and forth every once and a while?

> Interestingly, I had it on all weekend and on Monday it was rock solid.
>
> I shut it off last night and this morning, I am back to the same problem. Out of frustration, I checked the voltage on the 9v and 3.3v power supplies again. They were both at spec. So then I checked the voltage on the socket jumper on the back and it read 8.83v. So I took it out and put it back in. Now it reads 8.98v and it seems to be solid again.

Joe--If you dont have the TS-830s service manual it would be good to get it. On the x-ray view of the boards they list all the semi-conductor devices. D1 is a 1S1587, Silicon gen purpose, 200 piv that subs to a NTE 177.
D2 is a 1S2588, Silicon fast switching that subs to a NTE 519

Terry

Subject: Re: [TS-520_820_530_830] Re: TS-830S Low Receive and Little S-meter movement

Terry: exactly what I'm thinking. I don't want to take it apart again! I'm going to order a new NTE222 (K4EAA) to be on the safe side. but I have no idea what to replace D1 and D2 with? They test OK in circuit, but I'd rather just replace them while I'm inside. Any ideas on substitutes?

31624. ALC pegs on xmit and S-meter pegs on receive

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-05-31 23:52:10 UTC
From: srsigno
Topic: 31624 Message: 31624

I am having a cascade of problems with my TS-820 since I opened it to replace the S-meter bulbs. The first problem was a reduction of sensitivity on the receiver after activating the PTT switch. The meter pegged and gradually indicated a lower reading while the receiver a sensitivity increased. However, the S-meter did not move from near zero after that. I replaced Relay unit (X43 1190-00)but it did not fix the problem. Now the symptom has changed to something quite different. The S-meter pegs and does not move at all and the receiver sensitivity is extremely low. However, if I set the MODE switch to CW and flip the REC-SEND to switch to SEND with the meter on the ALC position, the meter pegs and gradually decreases to the normal ALC reading. Immediately after switching back to receive, the sensitivity is back to its normal level for a few seconds. Then the S-meter gradually goes back to max reading while the receiving sensitivity is reduced significantly. I would really appreciate any help that any member of the group could give me.

31625. Re: [TS-520_820_530_830] Re: TS-830S Low Receive and Little S-meter movement

Hi Guys,
Whenever I am testing a diode, I always lift one end and then use my
Diode tester to verify that it is good and no leakage.
Same with Transistors and Mosfets. You can test voltages when the
circuit is live, but trying to do the resistance test can give erroneous
results if done in circuit.
I have a L-41 apart here now on the bench. I am going to take pictures
and make a PDF file of step by step instructions on re-winding it.
Need to borrow the XYL's high dollar camera for nice close -ups..... LOL
The primary (6 turns) are wound on the lower part of the bobbin core
and the Secondary (26 turns) are wound on the upper part.
It is important to try and wind each turn NEXT to each other and not all
over the place. (make it uniform)
The wire is very easy to break, so don't be surprised if you have to
attempt it a couple of times to get it right.
The NTE222 is a good replacement, but be ready for sticker shock when
you buy one
Joe,
L4 went out in today's mail to you.
73,
Gordon
N6WK

31626. Burnt cathode resistors on a 520S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-01 02:58:21 UTC

Topic: 31626 Message: 31626

Hello all,
I'm back on the group after an absence and using my 520S again. Sunday night, during a ragchew on 14.273, I let the smoke out of my final cage. Visual inspection revealed the 10ohm, 1W carbon resistors on the final board were fried, one so bad I can't read the color bands on it. When this rig was given to me, the final board had 3 resistors burned under one tube. Those were replaced and it has done fantastic the few times I've used it. Now, one of the resistors that was replaced is burnt along with the same size resistor under the other tube. I've not yet tested the 6146B tubes but will before I try it again. Any ideas of what could toast a 1W resistor?

I also found 2 cracked diodes on the rectifier board and when I removed them, all but 1 came out in pieces. It was not the HV rectifier diodes but the 14V rectifier stage. I've replaced all 4 diodes with new ones now.

Any help would be greatly appreciated!
Erik

31628. BS-5 Bandscope Adapter

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-01 08:14:04 UTC
From: pakjan830
Topic: 31628 Message: 31628

Hi all,

I have a spare BS-5 Bandscope adapter (which allows a SM-220 station monitor to be used as a bandscope for a TS520, R599 or any other device which has a 3.395 MHz wide band IF accessible somewhere).

I can not fully test it as I do not own a TS520 but it works as expected in my SM-220 (not for sale) when fed with a 3.395 MHz signal from my signal generator.

If anybody is interested, let me know via PM please.

73, Jan

I am not sure if you will get this message but i am interested in the bandscope.
Not sure if you would send to VK but let me know a price and and we can go from there
Thanks David VK2DV

Subject: Re: [TS-520_820_530_830] Re: TS-830S Low Receive and Little S-meter movement

Hi Guys,
Whenever I am testing a diode, I always lift one end and then use my
Diode tester to verify that it is good and no leakage.
Same with Transistors and Mosfets. You can test voltages when the
circuit is live, but trying to do the resistance test can give erroneous
results if done in circuit.
I have a L-41 apart here now on the bench. I am going to take pictures
and make a PDF file of step by step instructions on re-winding it.
Need to borrow the XYL's high dollar camera for nice close -ups..... LOL
The primary (6 turns) are wound on the lower part of the bobbin core
and the Secondary (26 turns) are wound on the upper part.
It is important to try and wind each turn NEXT to each other and not all
over the place. (make it uniform)
The wire is very easy to break, so don't be surprised if you have to
attempt it a couple of times to get it right.
The NTE222 is a good replacement, but be ready for sticker shock when
you buy one
Joe,
L4 went out in today's mail to you.
73,
Gordon
N6WK

Allen;

Most everyone uses DeOxit D5 for the contact cleaner.

You may want to try cleaning the wiper inside the VFO with DeOxit D5. On
the right side of the VFO (from front of unit) is a cover held
in place with two screws. If you remove one screw and loosen the other,
slide the cover up, in the rear of the VFO is a wiper which
touches the Variable Capacitor and the frame. Try spraying this wiper with
DeOxit D5, and then move the VFO back and forth for
a little while. I have had this cause your type of problem before on the
TS-820. I guess over time, this wiper get dirt/grime and needs
cleaning to make good contact.

Regards and best of luck, 73s

Subject: [TS-520_820_530_830] BS-5 Bandscope Adapter

Hi all,

I have a spare BS-5 Bandscope adapter (which allows a SM-220 station monitor to be used as a bandscope for a TS520, R599 or any other device which has a 3.395 MHz wide band IF accessible somewhere).

I can not fully test it as I do not own a TS520 but it works as expected in my SM-220 (not for sale) when fed with a 3.395 MHz signal from my signal generator.

If anybody is interested, let me know via PM please.

73, Jan

Hello again I'm glad I found this group as all I own are Kenwood hybrids and this site has a wealth of info. Now the problem at hand. My 820s display has lost the center horizontal lines. IE. the 3's look like backward C's the 5's are missing the center horizontal line etc. Is the display on a plug in connector or is it soldered in? If it's plug in I would attempt replacing it. I assume that's how to fix it? If it's soldered I'll have to refer it to someone else. My soldering skills have become nil due to health issues. Severe hand shakes. Thanks for the help as I know that more than one person here will know how to fix it. In regards to a hybrid net. I'm interested in trying. Maybe we could just set a frequency to call on as it seems to be tough to get a set time? Thanks again. Richard KM5WX

The TS-820 display "tube" you are referring to plugs into the Display Unit through a multi wire connection. If you remove the top cover you will see the wires that connect to a plug that plugs into the Display Unit. The display tube itself is soldered to the small PC board that mounts behind the front panel. You might consider contacting Bob Mansker, ke5ftf at mail.com, he may have one.

Gordon: It would be great to see your progress with the L41 winding demo. I'm sure a lot of us would learn a lot from it! I have my parts ordered: NTE222, NTE177, NTE519, the #42 enameled wire and of course the L4 (coming from you). It will good to get my rig off the bench and back on the air! Thanks to you and Terry for all the patience and sage advice!

Here is status of getting permission to load newsletters on our site.

Contacted Rob N8RT former owner/editor. He has no problem with us doing this however when he sold INRAD he sold the copyright as well.

He told me to contace George Cutsogeorge W2VJN and ask his permission.

I sent George an email using the address I found on QRZ.Com and it comes back undeliverable.

Anyone know how to contact him?

Terry-K9TW

I would suspect that when George sold the INRAD business to the current owners, the rights to the newsletters went to these new owners. I can't see any reason for George to hold on to this information.

That would make sense but I wrote new owners first. Trey Garlough N5KO referred me back to Rob? So at this point after looking at all of the issues not sure other than the nostalgia and history that they would be of any value to our members. I think that is what you told me early on.

Terry,

Don't want to create more work for you... but you could always read the new letters and then publish a review of what is in them. I am sure that there is some good info in them; like wiring the fan to the heater switch. That seems like a pretty good modification to me. Anyway just a thought. Like I said... not trying to create work for you.

Dan-- I thought about trying to go thru and high lite only the 520, 820, 530, and 830 articles. I could then make an index of those articles and post it on here and if anyone saw something they were interested in I could summarize it to them Off List? It would be a lot of work. I havent given up yet on getting permission to copy them. Terry

Van--I had found this. It is advertisement from the company that put up Georges antenna farm (I am envious!). If you click on the link to Georges website it takes you to announcement that old INRAD website is replaced by new owners site. I contacted new owners and no luck with them.
Thank_Terry

Uses covered under limitations and exceptions to copyright, such as fair use, do not require permission from the copyright owner.

Examples of fair use include commentary, criticism, news reporting, research, teaching, library archiving and scholarship.

These are quotes. I would think that this use would fall under these circumstances.

Bernie--Thanks-- I am not sure what part of this we could claim? Each newsletter has specific prohibitions about "copying" and "reproducing". Appears that commenting on would be legal, but more work than I care to take on.-- I dont want for this to get off on an On List tangent or debate about copyright laws. Appreciate your efforts. Let me exhaust getting permission first and then we can let Group Owners to decide if they want to risk any legal ramifications. I have an email from Rob stating he has no problem with us uploading them , but I dont think he has a dog in the race any longer. Terry

Joe--It might be a good time to install a socket at Q1 the dual gate mosfet RF amplifier. It looks like there would be room. Would make any future repairs a lot easier. I suspect Mouser and/or Digi-key would have a 4 pin socket for the NTE222 package. Just a thought. I too am anxious to watch Gordons YouTube video!-- Terry K9TW

Topic: 31583 Message: 31647

I posted on this a while back, but as I was trying to get a grip on things, I had to rearrange my priorities. Now I'm back to square one it seems.

I have a 530S on the bench with good (tested) finals, plenty of ALC, and a hot receiver. I've replaced the screen and cathode resistors. When I tune the
radio, it's lucky to put out 1/2 w. It's also cooking a cap on the relay inside the final cage. The cap is from the lug (?) to ground. This cap and relay are what confuses me most. I can find several
sections of RL-1 on the schematic, but I see no designation for the second relay. This makes it tough to find my problem cap on the schematic.

With that cap gone, and most voltages checking within reason in the final cage, I'm wondering where to go next. I'm really not sure how to check voltages on the RF board either. Any tips?

Sorry for repeating my ignorance, but I hope to make this gem work! ;-)

Adam,
There are 2 relays in the 530, one on the IF board and one inside the final cage.

Looking at the530's main schematic in the serivce manual, the relay you are referring to is shown directly below the AF Unit board. This relay is located inside the final amplifier enclosure.

The other relay is located on the right rear corner of the IF Unit board.

The relay inside the final amplifier enclosure has a .01ufd disc cap connected across the relay's coil and the cap is labeled "C24". If this cap shorts internally then that relay will not energize because the relay voltage, 14VDC, will route/bypass the relay coil and short to ground.

The cap you are referring to, does it connect to the switch wafer inside the final amplifier enclosure? Other than the .01ufd cap across the relay coil, all the other disc caps connect to switch wafer S22-3 inside the final amplifier enclosure. If the cap does connect to the switch wafer than try tuning up on 15 meters to see if you get full output.

73s
Mike

31649. TS820 internal VFO

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-02 23:45:06 UTC
From: jdt970
Topic: 31649 Message: 31649

Im having trouble with the VFO. The outboard VFO works perfectly but the main VFO drops out, jumps Freq.,as I tune. when it is stable it drives the rig ok but it isn't stable very long.

I removed it to the bench and checked it with a scope and frequency counter. the wave form is lovely when its there. It will not go from 5Mhz to 5.5 Mhz. the hightest I can see is about 5.37 unmeshed. an about 4 somethine fully meshed. I sprayed the Cap wiper with contact cleaner. no help I applied pressure to the wiper against the shaft with a plastic tool, no help.

Looking over the schematic, I see that some of the resistors are a different value. For instance, there is a 1 meg where the schematic says it should be 100 ohms. there is a 1 meg resistor between the drain and source of the 3SK22 tacked on to the underside of the board. I tried replacing the 3SK22 with a 40673 and discovered that the pin markings on the board are in error. I reinstalled the 3SK22 and the 1 meg. resistor. I have got the same problem as before.

Has anyone run across this problem before?

Thanks es 73

WD0FTW (Jerry)

31650. ts-530 PA Band switch

my pa band switch went bad in my 530s and need to replace it ,anyone know where to find this part? MY TECH SAID ITS CRACKED AND ARCED REAL BAD AND IS NO GOOD ANY INFO NEEDED THANK YOU....

PLZ email me kd5utc@... or kd5utC@...

My pleasure Joe.
I am now almost done with my video for re-winding L-41.
I made an error on winding the primary and wound it clockwise instead
of counterclockwise, so I need to unwind the coil and re-shoot that part
of the video :-)

73,
Gordon

Topic: 31653 Message: 31653

Hi! Today I replaced the HV filter caps in my ts830m. The old black caps had a black spot on one of the terminals and I had it in my mind that these were Pos. I wired in the replacement blue ones accordingly. I think I have made a serious error because when I swithced the radio on the light went out and it appears to be "Dead". If the black topped terminals are actually Neg., then I have wired the caps in reverse polarity.
Can someone please confirm if this is the case and what if anything I might be able to do to put things right. I'm concerned I have made a bad situation worse. Thanks for any help/advice etc.. Cheers Jess

Gordon, I can't wait to see your demo. That will be so cool... and helpful
to lots of us who will eventually need to rewind the L41 to get our rigs
back on the air!

When cleaning and lubricating my newly acquired TS-820S, I lost one of the two 1/4-inch screws that mount the bottom of the VFO compartment to the bottom of the chassis. If someone has an extra screw I'd sure like to get one. Just call me at (509)427-4101 or email me at jimgoldring@.... Thanks!

Hi Jess,
You might be able to just re-wire the caps correctly and insert a new fuse.
I would certainly try that if the caps show now signs of damage such as
the bottom being swollen of cracked.
Let us know what you decide to do and what the results are.
Be sure to use ONLY a 6 amp fuse. Nothing bigger!
Another good device is the transformer saver. It is in the files section
of the group.
Very easy to build and protects the rig during testing.

Jess,
if you are running from 240 volt mains, the fuse should be 4 amp.
I assumed you were running from 120 volt when I stated to use a 6 amp fuse.
Not sure what voltage is used in the UK

Thank you Gentlemen! Despite my best efforts to blow this old radio up I have just finished a QSO with an old friend S51ZZ, who gave me a good report. I did what you said Don and things seem to be working fine. The meter light is not working but I can live with that until I can get a bulb.
I replaced the blown fuse and checked the caps which seemed OK and re-did the installation correctly this time.
It is very comforting having all this support and guidance that this forum offers. Many thanks to you all. Cheers Jess (G8IYE)

Picked up a 520 s today for $75.Receives great, have not tried transmitting yet but was assured it works fine. Cabinet is in good shape too. Serial number is 750516, any idea on when it was manufactored?

Also included was 2 dg-5s. One works, the other some of the leds are dead. Can they be repaired?

Thanks KB4MNG

Hi Everybody,

I posted about ordering new relays for my twins. They arrived and I installed them. The flaky operation of the receiver was corrected. The ALC in the transmitter is now applied but the 9 volt battery trick still will not get mine below about 10 watts. I can dial it down to around about 1 watt with the drive control but it's reassuring to see the ALC actually applied.

73,

Bill KU8H

Hi all,

  Just started looking for an HF rig. Want to get back onto HF.

  1st choice -- TS-520 or 530 series
  2nd choice -- TS 4xx series
  3rd choice -- TS-8xx series.

  Your input is welcome as well as anyone looking to sell. Did have a Heathkit SB-101 a ways back but circumstances required me to sell it.

Thanks,
John - WA2HIP

Topic: 31671 Message: 31671

Just bought a ts520s and pulled all the knobs to clean the gunk off. When I went to replace the knobs I discovered that the plate capacitor knob can actually turn completely in circles! Unfortunately I did not mark the position of the pointer and I am nervous that I will not find the dip quickly when I tune up for the first time.

Based on the 180 degree scale on the face plate, I assume the proper adjustment runs from plates completely meshed to plates completely open.

Can anyone tell me if the completely meshed position relates to 3.5mhz or would it be the other way around?

31674. suddenly weak TX on TS-830S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-04 20:20:11 UTC
From: ktwhy2003
Topic: 31674 Message: 31674

It was working fine last i tried transmitting a couple days ago. Just went to tune it up and I'm hardly getting any power output when I went to tune up...

On BIAS it's only showing 20ma now (mode USB, meter IP)
and all the rest of the tune up process is correspondingly low.
I'm tuning in to the dummy load of my MFJ-949E I did ad a basic lightning arrester out on my antenna this past week, but that's not involved in the tune up of course, and I was on the air a few days ago since adding the arrester. Could it have damaged my radio?

31675. TS 530 verses a TS 130

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-04 20:16:16 UTC
From: Brian
Topic: 31675 Message: 31675

Along with my 520s I also purchased a TS 130. I was told the ts 130 is a mobile version of the 530. I find that hard to believe. Is the receiver in the TS 130 on the same level as the hybrids?

Thanks KB4MNG

I seriously doubt the lightning arrestor has anything to do with your problem.

You didn't say what the HV meter indicated when the 830's tuned for maximum power output (Red meter scale).

Also, what is the IP meter showing at maximum power output (top meter scale).

It's also possible the AF Unit relay is going bad, not unusual for this relay to fail and affect transmit and receive. You might try tapping lightly on the AF Unit relay when keying the 830 in TUNE and/or CW mode. If power output changes, increases, then replace the relay on the AF Unit board (see Ken, K4EAA, for details on replacement AF Unit relays).

400 volts on the HV

about 125ma on CW send mode. so both about half normal.
I'll check the rely after dinner, don't want to be opening it up while cooking.

Topic: 31675 Message: 31678

This sound more like a personal opinion than fact from Kenwood. Although the TS-130 has the same band coverage and "similar" power rating as the TS-530, I've never heard or read where the TS-130 is Kenwood's "mobile" version of the TS-530.

The TS-130 has a sideband PEP input power rating of 200 watts and a CW DC input power rating of 160 watts.

The TS-530 has a sideband PEP input power rating of 200 watts and a CW DC input power rating of 180 watts.

The "20 watts" DC input power difference in CW mode between the TS-130 and TS-530 will not make any difference at the receiving end.

The TS-130 receiver, with appropriate filters installed and assuming the TS-130 is aligned properly and operating according to specifications, is quite similar, if not equal to the TS-530. Operating mobile will not, in many cases, produce the same as operating from your house. Antennas, type of antenna used, radiation patterns, and physical location play a role in efficient mobile operation.

If the HV is only 400VDC then one of the HV filter capacitors has failed.

I recommend replacing both HV filter capacitors with new caps, obtained from Ken, K4EAA. Don't forget to replace the two 470K 1/2 watt resistors and .01ufd disc capacitors with new components along with new HV filter caps. Ken, K4EAA, sells a HV rebuild kit which as all these components.

When you replace the HV caps, pay attention to the leads. Remember, "BLACK" on the HV cap terminal means "Negative" NOT "Positive". Some caps have a strip down the side of the capacitor that points to the "negative" terminal. If you have a high res digital camera, take a picture of how the leads of the failed capacitors are connected. The HV supply in the 830, just like all the other hybrids, is a voltage "doubling" supply. The two HV filter capacitors are wired in "series" NOT "parallel"!

If there is any doubt in your ability to perform the capacitor replacement, locate a local ham who has experience and knowledge to help you. Don't try it if you have any doubt you can do the job successfully and "safely".

If you do it yourself, thoroughly check your work to ensure the capacitors are connected properly BEFORE you apply power! Don't be in a hurry, take your time.

Your problem appears to be the HV filter capacitors. For now, replace the HV filter caps and I suspect your problem will be solved. The AF Unit relay does not appear, at this point, to be the source of your problem.

THanks for the info. I'm pretty good with a soldering iron, been into electronics since I was 7, now 44. There's a guy that sells the kit on ebay that's an hour drive from here, may just see if I can go buy them from him since there's a postal strike on in Canada right now. I won't want to have it hung up some place for weeks..

I rewound L41 and installed the L4 that I received from Gordon. I carefully installed the RF board and reassembled the radio. There is some improvement...I can hear signals and the S-meter is responsive. Problem is the the AF volume control needs to be nearly fully clockwise to get a nice full volume. Before the initial problem, the volume was comfortably loud with the AF control at 9 o'clock.

Maybe I didn't do a great job at rewinding the L41? I'm not sure how critical the windings are...then again, maybe there's another issue.

Joe--How is the crystal calibrator (marker/MKR) volume? When you turn it on and tune to it do you have to reduce the AF Gain? Do you have a signal generator? In absence of generator apply your finger or jumper clip lead to VC-1 and VC-2 as you previously did-- Terry

Terry... it seems I've got more problems than the lower, but improved receive. Now I have no RF output.

I must have made a mistake or misalignment of the shafts in reassembly. I made notes as I took it apart and followed the notes when putting it together. I'm able to peak the drive on the ALC meter when in Tune. But, I'm unable to get a dip in plate current. Turning the plate control has no effect at all. I'm going to go back inside and see what I've messed up.

The calibrator volume seems loud to my ears, but on any band never moves the meter beyond S7.

Joe--Alignment of RF board bandswitch S1 to PA cage bandswitch S22 is critical. Mike W5RKL has posted detailed step by step several times. You can search archives for it. I would not attempt anymore loading until you assure S22 has been re-coupled correctly. If not, can damage finals.
Get RF output fixed and then go back to low receive. Terry

Terry... it seems I've got more problems than the lower, but improved receive. Now I have no RF output.

I must have made a mistake or misalignment of the shafts in reassembly. I made notes as I took it apart and followed the notes when putting it together. I'm able to peak the drive on the ALC meter when in Tune. But, I'm unable to get a dip in plate current. Turning the plate control has no effect at all. I'm going to go back inside and see what I've messed up.

The calibrator volume seems loud to my ears, but on any band never moves the meter beyond S7.

Joe,

It appears you have the band switch S22 switch shaft and long band switch shaft out of alignment.

Remove ALL power to the 830.

Ensure the HV capacitors have bled down to zero.

Place the 830 with the front panel facing you.

Remove the final amplifier cover.

Remove V1, front 6146.

Set the band switch to the "10Mhz" position. That is not 10 meters.

The switch shaft on the switch inside the final amplifier has 2 flat spots. With the band switch set to 10Mhz, one flat spot must be exactly vertical on the right and the other flat spot should be exactly horizontal on the bottom.

If this not how the switch assembly shaft inside the final amplifier is in your 830 then the long band switch shaft is out of sync with S22 switch assembly shaft inside the final amplifier enclosure.

The flat spots I am referring to are on the short S22 switch shaft NOT the long band switch shaft.

Joe,

If you continue tuning the transmitter with the band switch out of sync, the plates on "both" 6146s will turn RED and you can easily damage not only the final tubes but also the HV supply and possibly other components.

If you can't find the steps to align the band switch, drop me an e-mail and I'll give them to you. It's not difficult.

John --I thought one of our members might know him and have his current email address.

I did the white page searches (people, phone etc) and came up empty.

I will snail mail him using the address on QRZ.com.

After looking at the newsletters I am glad I got to see them and will hang on to them. However, someone who was familiar with them posted that much of the info contained has already hit the internet especially the mods and there would not be much value to our members to have access to them.

If snail mail fails then I think that is where we will be at.

Mike,
The short shaft inside the RF cage has two flat sides opposite of each other. I'm confused when you say the flat on the right should be perfectly vertical and the flat on the bottom should be perfectly horizontal. What am I missing? Also since the control will rotate 360 degrees, how do you know it's not 180 degrees out of sync? I don't mean to thick headed.
Thanks,
Joe

Joe,
I have NEVER seen a TS-830S final cage band switch that had the flats
opposite each other. They have always been exactly as mike stated.
The long shaft coming through from the front has the flats on each side,
but the Final cage output band switch has them at 90 degrees apart.
I can send a picture if needed

73,
Gordon

Joe,

Make sure the HV filter capacitors are discharged to zero before continuing.

Remove the top cover of the 830 then remove the top cover of the final amplifier enclosure.

Remove V1, front 6146. Removing V1 gives you a clear view of the band switch coupler and the shaft of switch S22's shaft.

Switch "S22" is inside the final amplifier enclosure.

If you look closely you will see 2 flats on the shaft of switch S22. You can easily see them by rotating the band switch and watch as the shaft of S22 rotates. Once you see the flats and how they are on switch S22's shaft then all this will make sense.

Just remember, do NOT set the band switch to 10 meters!! A number of hams have confused "10" on the band switch to mean "10 meters" but that's not true!! Setting the band switch to "10" is "10Mhz" NOT "10 meters"!!

I agree, Gordon, send him the picture. This will help him understand what we are talking about, the flats on the shaft of S22.

Joe,

Is this with the band switch set to "10" on the front panel?

One additional comment. You will need a "1.5mm" metric hex tool to loosen the set screws on the band switch coupler. A normal hex tool will not work. You can typically purchase metric hex tools at most hardware stores, that's where I bought mine. A set cost around $6 to $8.

Hi Chris and Joe,
Attached are some pics that should help.
I have tried to use arrows and labels to explain. The switch i used is
out of the radio but hope this clears it up

73,
Gordon

Thanks Gordon,
I finally located the flats on the short shaft inside the RF cage. They are as described and as your photos show. When I aligned the vertical on the right side and the horizontal on the bottom and positioned the front dial to "10" -- when the rig powers up the digital display is way off and doesn't align with the band numbers on lthe front of the dial. I sent an email to Mike about this... I think I'm still out of alignment.

Sounds like maybe you have the front shaft 180 degrees out
What does the display show when you are on the 10 MHZ position ?

Gordon,
The display reads 29 mhz in the 10 mhz position -- 28 mhz in the 7 mhz position... You're correct: 180 degrees out on all positions. What I don't understand is why the rig won't tune when the dispaly is reading 7 mhz? What would it matter what number the knob is pointing at as long as the frequency display is correct? Seems like I could just loosen the knob and turn it to the correct number?

Joe,
You must loosen the front set screws on the coupler, slide the shaft completely out of the front section, then rotate the shaft 180 degrees, re-install it into the RF board and slide it into the rear coupler and then tighten the screws.
Everyone of the wafers on the RF Board band switch MUST be in the correct position as well as the output band switch for the radio to work properly.
Each one of the little white center pieces of the Rf Board band switch Wafers has a small DOT and a Notch on them. They all have to be orientated the same way as well.
For me, it is a 5 minute job, but then again, I have done dozens of them

Gordon,
I understand that... and will do. I wonder if some how I got the wafers themselves misaligned. I did insert the shaft to turn the wafers when I cleaned them with a little deoxit, when the RF board was out on the bench. How can I double check the white dot and the notch? How should they be orientated when the shaft is inserted correctly and the pointer is on "10"?

Joe,
Let us know how it all comes out after everything is aligned. Don't
forget, you will have tpo adjust the L-41 after it was re-wound as per
the service manual on 1.900 mhz
Bedtime here now :-)

31707. Re: [TS-520_820_530_830] Re: TS-830S Low Receive and Little S-meter movement

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-06 14:38:53 UTC
From: Joe Loverti
Topic: 31519 Message: 31707

After a ton of help from Terry, Gordon, Mike and others I was able to remove the RF board, rewind the L41 transformer and finally get the band switch shaft reinstalled correctly. The audio is much improved and the transmit output is restored to normal operation. I must have gotten the band switch wafers on the RF board turned upside-down while I was cleaning them with deoxit. I used the shaft to rotate the wafers switches as I was cleaning them and didn't pay attention to how they were oriented. When I reinstalled the RF board the wafers switch were 180 out of phase. I was lucky to not do any damage in attempting to tune the rig with the switches and shaft alignment incorrect. Thanks again guys for your patience and for teaching me a little about the Kenwood TS-530S.

Would it be possible to put a little dot of red marker ink on each of the wafers before disassembling the switch, so there would be no guesswork involved when reassembling the thing? I am not familiar with this particular switch, but I do know that with many stacked wafer switches it is a distinct possibility to mark them in some manner. Just curious.

Jim,
Gordon pointed out to me and sent me a photo showing tiny notches on the outside rim of each wafer switch. Had I known that beforehand or bothered to mark them as you suggest, I would not have made that mistake. It's a lesson that I won't forget!
Thanks,
Joe

When trying to set idling current on my TS-830 to 60ma meter deflects slightly to left. Triple checked all control settings. Pot adjustment makes no difference in amount of deflection. Voltage on middle connector of SG switch reads 12.25 VDC, relay on rectifier board audible when SG switch moved. Receiver side seems ok no xmit. Ant ideas.

Have you tried replacing the final tubes? From what you are saying it appears one or both of the final tubes have an internal short between the cathode and grid allowing the final tube bias voltage which is negative to be applied to the metering circuit which is causing the meter to deflect below zero (to the left).

Got the new caps for the radio today, and took a lot of pics installing them. Probably post them on my website and here when I have time. My high voltage is back where it belong and a solid 100 watts on a CW send.

THANK YOU for pointing out where the problem was for me.

next project is fixing the power switch soon as the one i ordered gets here..An interesting discovery though, I found a single thin blue wire cut and taped on the bottom near where the caps are..
and it has the CW filter YK-88C installed. not that I do CW, but nice to know.

Probably the cut wire for the WARC bands. This enables you have have 17
meters, etc.
Chuck KJ4GU.

31714. Speech Processor alignment question.

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-07 04:25:30 UTC
From: Chris Parnell
Topic: 31714 Message: 31714

Hi all,

After aligning the rest of my TS-830s I went to do the Speech Processor alignment as per pages 40 & 41 of the Service Manual.

States:

SG SW = Off
Mode = USB
Meter = Comp
Mic Gain = MIN
Proc = ON

Connect AG output (1.5kHz, 5 mV) to the Mic Jack, Set the STBY switch to Send and adjust Comp Level control until the meter reading is obtained.
Adjust L26 for Max. Meter Reading.

Done all of the above and all is well.

Next step:
Set VR5 on the IF unit fully clockwise and adjust the COMP level control until the meter indicates S-1. Set the AG output to 50 mV
VR5 Meter indicator 20 dB.

Done all of the above and all is well.

Next step:
Meter to ALC, Adjust Mic-Gain control until the maximum meter reading is obtained.
L276 Maximum meter reading.

Done all of the above and all is well

Next step:
Set the PROC to OFF and set the COMP LEVEL control to maximum. Set the AG output to 10 mV.
Adjust the MIC GAIN control until until the meter indicates the maximum on-scale ALC reading. Set the PROC to ON.
L27 - Adjust until the same meter reading is obtained (MAX ALC on-scale)
Mic input providing the SAME ALC meter reading 10 mV (+/- 3dB).

This is where my 830 (or me) gets stuck☐..
Every step works until I get to the point where I turn the Proc ON and adjust L27 for the same reading as where the PROC is off.
On adjusting L27 with the PROC ON I get no movement on the meter at this point, and therefore cannot obtain the same ALC maximum reading.

Any help would be gratefully appreciated.

Thanks
Chris, ZL1CDP

The "A" is to designate a faster warm up for the tube (approximate 11 seconds).

The 'non A is supposedly longer.
How much longer probably will not matter.
Most of us turn on the rig and wait 5 minutes for it to settle down anyway.

Charlie

Chris--Did you get an answer to this?

I have not performed this step. I am stuck on Step 31 ALC adjust. I can do Step 1 and adjust VR6 for exact zero but cant do Step 2 as written with mic gain set to max as it pegs my meter hard with 5mv signal injected at mic connector. I have to reduce mic gain to get max full scale reading and then reduce it further to see 5 watt power reduction. I have found that some of these steps cant be performed as written. Because of this and test equipment limitations many(ok-some)of the fellows just perform the Sect 6 maintenance adjustments and a few select Service Manual steps. Setting voltage regulators, carrier adjustments, are all commonly done. Hard to do PLL BPA if you dont have good sweep generator and good scope. Also, spectrum analyzer is beyond reach for many. I watched an experienced kenwood tech adjust VBT oscillator by simply adjusting TC-2 to exactly 8375.0 khz. That is ok if it was grossly out, but real adjustment is described on Pg 38 with two methods that are more complex. I have used these steps and my VBT oscillator in 2 different 830s is set from about 50 to 100hz higher than 8375.00 to align the filter passband windows.

If I ever get past Steps 31 I will move on to Step 32 and give you my results. If you get it figured out I would appreciate you sharing it with me. Good Luck --Terry K9TW

If I use the plate and load setting to reduce my power,would I be causing any damage to my 520? Or is this a normal way of controlling your output?Thanks for reading..Jes-m0jsw

31720. Instability on one band, 20m, only

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-07 11:03:59 UTC
From: Bernie
Topic: 31720 Message: 31720

Hi,

I bought a TS830s a while ago with several faults. Its now down to just one issue. On 20m, with no carrier at all, in CW mode with key down, when I sweep the plate control across the 20m section of the dial the PA takes off and current is at max on the Ip meter. I drop the key instantly as obviously don't want to se this through to its obvious conclusion!

Background:

I replaced valves with 6146B by GE from a well known reliable source. Same with driver valve.

I neutralised according to instructions.

I checked values of several components in the PA circuit - the cathose resistors, the SG voltage - everything normal. No signs of overheating/damage.

Prior to changing out the tubes I could tune the rig up and use it, but after a few minutes of use the fuse would blow. I figured the old tubes were arcing which is why I decided to change all.

I'm getting 100w on all bands easily although on 20m, tuning up is not easy. The dip seems broader than usual. Tuning for max power never gets me there, only very careful adjustment looking for the dip gets me to 100w with 265mA current. Tuning for maximum power always seems to result in excessive current.

On 28Mhz max power out coincides exactly with Ip dip.
On 24Mhz plate dip results in 80% of power available by tuning for max.
On 21 Mhz plate dip coincides with max power
On 18 Mhz plate dip coincides with 90% of max power out available.
On 14 Mhz plate dip coincides with 75-80% maximum power out.

I've done a few CW contests in recent weeks with the rig (what a beautiful, beautiful RX with the 250Hz filters !!!!) and I can get everything working - even on 20m.

BUT I feel something isn't right and I want my nice TS830s to have a happy life. It should not take off the way it does on 20m and the tuning is very difficult to manage on this band.

I've been a reader of the group for some time and I've looked through a lot of posts and there are similar issues out there but I haven't seen anything that is exactly like this and I'm not sure what to do next. I'd be really grateful for any ideas.

Thanks

Bernie

Thanks Mike

I have replaced the tubes with a known good set from another kenwood I have. With the Final tubes removed the meter still deflects to the left. Since my last post I checked driver tube voltages they are

Pin xmit rec

1 4.6 0

2 0.4 43.6

3 0 0

7 346 346

8 256 256

measured from top of board with tube removed.

Thanks Gary

Hi Gary,

The driver tube voltages appears to normal. I assume pin 2 voltages are -43.6VDC in receive and +.4VDC in transmit. Your voltages appear to be positive but I suspect you forgot to put the "-" sign next to the 43.6VDC and the "+" sign next to the .4VDC. That's what the normal driver tube grid voltages are.
When you say the IP meter deflect below the 60ma mark, how far below doe the meter deflect or is the meter deflecting "below zero" in transmit?

Hi Jes,

You should never improperly adjust the PLATE and LOAD controls to reduce power output! Always adjust the PLATE and LOAD controls for full power output. By adjusting the PLATE and LOAD controls for a reduced RF output you are de-tuning the PI Network to an "out ot resonance" state which will result not only in higher final tube plate current and an increase in anode (plate) heat in both tubes but also you run the risk of an increase in harmonic radiation plus addes "undue" stress to the power supplies on the Rectifier Unit. As to whether you would be causing harm to the final tubes the answer is yes.

You can also reduce power output by applying a negative DC voltage between 1.5VDC and 5VDC, to the REMOTE socket's "ALC" terminal and ground. See the "Files" section of this group for circuits that do just that, there are 2 circuits, one with a pot and a 9VDC battery and one with a transistor, pot, a resistor or two, and a 9VDC battery. The transistor circuit is much more linear then the pot and 9VDC battery circuit.

To reduce power in CW, after properly tuning for maximum power output, adjust the CAR control CCW for the power level you want. In sideband, adjust the MIC gain for the power level you want.

If you are driving an amplifier and you need a lower power output, build an RF attenutator and place it between the 830 and the amplifier.

Bernie--Yes receiver is really good. I have full filtered and CW receive is best I have ever had.

It sure sounds like it is taking off on you. Is it possible you are losing bias?

Have you tried neutralizing on 20 meters? How are you neutralizing (with scope, RF millivolt meter to see the null?) as opposed to trying to match dip and max output power.

I would try to load up on 20 meters. Keep IP at around 100 ma if you can. You will likely see one side of your dip rise more abruptly on one side than the other. Set your plate control to that side slightly and then adjust neutralizing cap. May have to repeat several times to get a smooth and equal rise on either side of max dip.

Do you have a nice smooth and equal rise in dip on say 40 meters?

Terry-K9TW

Hi,

i found myself exactly in the same situation: simply inject 50 mV instead of 10 mV as stated in the service manual and you will get enough meter to align it. At the end you are balancing proc on vs. proc off positions.

73's Joe.

The pointer is slightly above the "0" point in receive and deflects "below zero" durning transmit. When the radio was operating properly the pointer rested on the "0" mark. I t seems that there is a small signal causing the pointer to rest above "0" in receive and when you switch to transmit something is shorting and causing the pointer to deflect "below zero". Since my last post i also removed the driver tube and the pointer still deflects in transmit. I have cleaned RL-1 on the AF board it clicks but I don't know if it is working properly electrically.

Thanks gary

Thanks Terry,

Bias: When I checked the bias voltage it was ok so if its losing bias I think it must be a momentary loss and I'm not sure how to spot it. I have a digital scope with a one shot trigger so I can probably set it up to catch any fall. I'll be thinknig about this over a cup of tea (us brits never change....) and will have a look shortly.

Neutralising. Not tried neutralising it on 20m but your description of a symetrical dip already applies - I just checked it. It seems a bit broader than on other bands but perfectly symetrical.

Still on neutralising, I used a 50ohm dummy load and a scope to minimise rf waveform on 28Mhz.

Before I look at neutralising specifically on 20m, a friend of mine has suggested something else as a possibility. He tells me that the GE valves might have a higher gain than the original Japanese ones and that there is nothing actually wrong, other than a little too much gain causing instability on one band. He suggests putting one (unbypassed) 10 ohm resistor in series with the existing cathode resistors to provide a little negative feedback. He used to do professional high power RF design and, well lets put it like this, like many in this group he knows a lot more about it than me.

But I prefer not to mod the rig unless there's a few experts out there that support the idea and a quick google doesn't reveal that anyone has felt the need to do this before.

Bernie--Yes receiver is really good. I have full filtered and CW receive is best I have ever had.

It sure sounds like it is taking off on you. Is it possible you are losing bias?

Have you tried neutralizing on 20 meters? How are you neutralizing (with scope, RF millivolt meter to see the null?) as opposed to trying to match dip and max output power.

I would try to load up on 20 meters. Keep IP at around 100 ma if you can. You will likely see one side of your dip rise more abruptly on one side than the other. Set your plate control to that side slightly and then adjust neutralizing cap. May have to repeat several times to get a smooth and equal rise on either side of max dip.

Do you have a nice smooth and equal rise in dip on say 40 meters?

Terry-K9TW

Just noticed the IP is running at about 40ma? Is this normal after a repair of this kind? Just want to know before I try turning it up on the back of the radio. Tuning in to a dummy load on 20m.

> >
> > When you replace the HV caps, pay attention to the leads. Remember, "BLACK" on the HV cap terminal means "Negative" NOT "Positive". Some caps have a strip down the side of the capacitor that points to the "negative" terminal. If you have a high res digital camera, take a picture of how the leads of the failed capacitors are connected. The HV supply in the 830, just like all the other hybrids, is a voltage "doubling" supply. The two HV filter capacitors are wired in "series" NOT "parallel"!

Bernie--I dont know how you would get an unbypassed 10 ohm resistor in series with the existing 4 parallel 20 ohm resistors. Perhaps cut the circuit foil at the cathode and bridge it with the 10 ohm resistor. I know I would never do that on my rig. There are hundreds if not thousands of these rigs in service without need for negative feedback mod. If you can get a hold of another set of tubes try them. One of the GE tubes you just put in may be gassy and causing current runaway? Resting plate current is different than bias. If you have the covers off you can monitor bias voltage at FG terminal on the RF board. Pretty well exhausted my suggestions. Others please jump in. Good luck--Terry K9TW

Bernie--I forgot to mention if you do monitor Bias I would use both a Scope and VTVM. Scope to see if you have AC ripple. There is difference between instability where tube breaks into oscillation (VHF or HF) and tube IP current drifting high and ultimately blowing fuse. The more I think about it your description is more the latter? If so, I would take a hard look at Bias. Still wont hurt to re-neutralize on band where you are having the problem. If that doesnt help you can go back and neutralize on 10 meters. Terry

Topic: 31720 Message: 31733

Thanks Terry - that's quite a few very good suggestions and I'll follow them all over the next day or so when I can get the bench cleared.

I fell in love with the rig that much that when I bought the tubes I actually bought two pairs so I can just try swapping the tubes out too.

Will report back with, I hope, a success story.

73 and thanks again for taking the time and trouble to help.

Bernie --Please do report back especially what you found to fix problem so we can all learn from it. I think most of us on here fell in love with these classic rigs. I have never operated a modern DSP rig or SDR and I am sure they are fine, but something about real knobs and dip and load has big attraction for me. Besides performance I just like the way it looks. 73s Terry K9TW

31735. TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-08 02:05:11 UTC
From: ww8x_joe
Topic: 31735 Message: 31735

I hope you guys aren't tired of this topic yet? Anyway, if you've been reading the threads related to my adventures with my low receive problem, I discovered an important clue.

When I take an 18 inch test lead and connect it to one of the lugs on variable capacitor VC1 I hear fairly loud signals. When I connect the same test lead to my outside antenna feedline to the one of the lugs on VC1 the signals jump up very loud with normal noise and S meter readings at S9 and above -- just as the set used to have before my problems started. Here's the curious thing: When I connect the same test lead that's connected to the antenna to the center of the SO239 antenna jack on the rear of the rig... the signals drop way off as if there's hardly an antenna connected. So in addition to having to rewind the L41 (which I've already done), there apparently is also something going on with my receive. I think I'm on to something. What do you think?
Thanks,
WW8X
Joe

Joe--When you touch center conductor of your antenna coax to stationary plate lugs of VC-1 or VC-2 you have bypassed the new L4 and rewound L41 transformer. You are down stream of them. You are coupling signals directly to the gate of receive RF amp Q1. It proves Q1 and D2 are good. (I believe you replaced both?)

Try touching ant coax center conductor to TP-1 on the RF board. You will be on "input" side of L4 and L41. If your signal is weak when touching TP-1 it means something wrong with either L4 and/or L41.

If signal still strong at TP-1 then move to Pin 3 labeled ANT on Connector 3 of RF board. Gently wiggle Connector 3 while applying center conductor of antenna coax. If signal comes and goes you have bad solder joint or bad foil at that connector.

Use your schematic and keep working your way back to your SO-239 connector on rear panel. Next place would be RF attenuator switch. Then Xverter connector switch , then antenna relay RL-1.

I had asked you about Xtal Calibrator or Marker signal and I believe you said it was down as well. If Xtal calibrator signal is strong then L4 and L41 are OK.

Terry:
Interesting. Touching the antenna to TP-1 drops the signal way down. So, I guess I still have a problem with L4 or L41? I adjusted the L41 to Gordon's suggestion and was able to get a 20+ db calibrator signal reading at 1.900mhz by turning its slug slowly. Which makes me think I did OK with the rewinding. I don't think rewinding it again would make any difference? I am certainly willing to do that if you think it would be helpful. The L4 was a replacement Gordon sent me and have no reason to believe it's not working. I checked it for continuity and it seemed fine. BTW, I ordered a NTE222 and a replacement for D1and D2 on the RF board, but haven't received them yet. At this point I think I'll just save them as spares, because as you state, Q1 and D2 are good.

It was great to hear the receive come back alive when touching the antenna to VC-1, now I just have to come up with a permanent fix. Baby steps :?)

Thanks,
73

31738. dg5 counter displaying 999999

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-08 06:58:34 UTC
From: lw8eoq
Topic: 31738 Message: 31738

Hello,

I'am currently trying to get a dg5 counter to work. Checked a lot of solder points, thru holes, etc.

I have it running now, but in counter mode it reads 99.999.9 with only the power cord connected. On display mode I only see the dots. When I connect it to the 520S, I also get 999999 on display mode.

I read other posts regarding power failure causing power resistors to get hot. I noticed that they do get warm... is it ok? Maybe I would have to check that too. It is 4 a.m. and I give up for today.

Thanks in advance for your kind assistance.

Hey Joe,

Haven't read all the thread, but sounds like a relay that is burnt out, it's in a metal case, will have a look at a diagram and revert back shortly. Only reason saying that is I did a stupid thing about 25 years ago to my 530s, tune it up without a load and the relay died, cost me $90 back then!!

Hi Mike,
"In sideband, adjust the MIC gain for the power level you want."
Did you mean for PSK?
(Previous posts have indicatedthat in SSB voice mode, the MIC control should not be used for power reduction)

Joe--Normal failure at Connector 3 Pin 3 would be a loose or intermittent connection and not a short to ground. So if signal is weak applied at TP-1 it points downstream from there. Only place you worked was at L4 and L41.

What is confusing me is --Are you getting good marker signal? Have you tried it on bands other than 1.9?

If you are getting 20 over marker signal and can peak L41 your rewind and re-solder sounds good.

With 20 over marker signal on 1.9 you should want to turn AF gain down as volume would be rattling the speaker. Same for any other band. If this is true then you know L4 and L41 are ok. I would try marker on 20 (14.175) meters. With it on peak the drive for max s-meter reading. If you dont want to reach for AF control to turn down the volume then adequate marker signal is not passing L4/L41.

Only other components in signal path between TP-1 and L4/L41 are coupling caps C1 and C3 and associated filter network caps/coils. Would be very rare for any of these to fail.

I guess you could take a jumper from Pin 2 of Connector 4 and inject your marker signal at stationary plates of VC-1 and see if marker signal increases significantly?

Terry

Hi Dave,

You said

"Did you mean PSK?"

No I was not referring to PSK.

PSK and normal sideband voice both use the same speech amplifier. The output level of the speech amplifier is controlled by the front panel MIC gain control. By varying the MIC gain setting the transceiver's RF output is controlled. That was the sole purpose of my statement regarding RF output in sideband mode, nothing more. This can be clearly seen when operating PSK since PSK uses the same speech amplifier that normal sideband voice uses and by varying the MIC gain, the transceiver's RF output is varied.

The Kenwood hybrids do not have the same RF OUTPUT control that modern day menu driven transceivers have. That leaves the MIC gain and ALC as the 2 players in controlling RF output in sideband transmissions with the hybrids.

Hi Mike,
I thought the purpose of the homebrew 9v circuit was to adjust power in SSB without changing the alc action on voice peaks.
I read in previous posts that turning down the mic gain to reduce power can degrade audio. (see Message #19563 and others)
At my age, I probably couldn't tell the difference anyway.
Thanks
Dave

hello folks.

just one question.

on tuning,

(plate part)

the 80m is the bar all the way up, right?

not only up to the ' 7 ' part.

it goes past that, am i correct?

thanks.

john

Hi Dave,
If you really think how the battery circuit works and how it controls the first IF amplifier's gain (Q1) in sideband transmit and how ALC controls the gain of Q1, you will see it works exactly like the RF Gain control and AGC voltage does in receive in controlling the gain of first IF amp Q1. The RF Gain control also controls the gain of the RF Unit's receiver RF amplifier but since we are talking about transmit, I'll stick with Q1 on the IF Unit's gain control.

Take, for example, if you adjust the RF gain control CCW to a point where the S meter rises to and stops at S9. You have been listeing to an S5 signal and you should still hear the S5 signal but the S5 signal doesn't cause the S meter to move. Why? Because the RF Gain control is controlling the gain of Q1 on the IF Unit. By controlling the gain of Q1 you also control the production of AGC voltage.

By adjusting the battery and pot in sideband transmit to a point where the peak RF output is say 25 watts, I seriously doubt there will be any ALC produced. Therefore, at 25 watts peak RF output which will not result in ALC being produced, the idea that the battery circuit does not affect ALC production is not true. Remember, by reducing the gain of the first IF amplifier Q1 you also reduce the level of the 8Mhz "TIF" RF signal that is applied to the transmit mixer. By reducing the TIF signal level you reduce the level of RF output from the transmit mixer, driver tubes, and ultimately the RF drive to the final amplifier, hence a reduction in RF output. By reducing the peak RF output you also affect the production of ALC because the level of RF applied to the final tube grids from the driver tube is such that the grids of the final tubes never swing positive, hence no grid current and no ALC is produced. So, yes the battery circuit can affect/reduce/eliminate the production of ALC.

The 80 meter front panel "arc" covers no only 80 meters but also 40 meters. Depending on the 80 meter frequency determines the approximate position the PLATE knob pointer will end up pointing at when the IP dip occurs. If you tune up at the top of 80 meters, say 3.980, the PLATE knob pointer will be pointing more towards to top end of the arc while tuning up on the low end of 75 say, 3.525, the PLATE knob pointer will point more towards the bottom end of the arc.

The same applies to 40 meters, 7.290 the plate knob pointer will point more towards the top of the arc while 7.025 will point more towards the middle to lower area on the arc.

Terry:
At 14.175 mhz with the drive peaked, I get an S7 calibrator reading. Quite different than I get 1.9 mhz -- you're correct, it buzzes the speaker. I'll try your other suggestions when I get a chance later on this evening. I probably should think about checking the relay as Dave suggested.

One other thing that may be related, is that when I'm on a strong signal the S-meter fades. In other words, as it is now the strongest signals are around S7 or so... when I tune on them by watching the S meter, after a few seconds the S meter drops off and comes back up and drops off. When I connect the antenna to VC-1 lug the S meter does not fade -- nor does it fade on the calibrator signal.

From: Terry Wagoner
Topic: 31735 Message: 31748

Joe--If the Marker is "buzzing" the speaker with AF gain wide open I would say that L4 and L41 are ok. On my TS-830 I get about 10 over S-9 on 80, 40, 20 with driver peaked. Maybe around S9 to 5 over on the higher frequencies. In all cases I need to turn down the AF gain when Marker is on and Drive is peaked.

1. There are 3 possible failure modes 1. Open signal path 2. Shorted or Shunted signal path 3. Intermittent signal path (doesnt fit your symptoms)

2. We have determined that signal path from Marker to Speaker is good/normal.

3. We have determined that signal path from VC-1 is good/normal (including AGC action?)

4. We have determined that signal injected at TP-1 produces significantly weaker output. What components and what failure mode are in path from TP-1 to VC-1?

5. L4/L41 share path with Marker and antenna signal and Marker is good therefore L4/L41 are good.

6. When you apply coax signal to TP-1 you say signals are much weaker than when touched to VC-1. As I mentioned the coupling caps and what I believe are band-pass components (probably broadcast band?) are the only components in path from TP-1 to L4/L41. These components typically dont go bad. These components are not in the circuit when you use the Marker.

7. So, is it possible that something is shunting/shorting the signal to ground at TP-1?

8. Can you unplug Connector 3 carefully and then re-apply coax signal to TP-1? If signal comes up to near same as when touched at VC-1 then you know coupling caps and band-pass filter components are all good. The fault then has to be something shunting the signal to ground upstream of TP-1. If signal does not come up, then coupling caps, bandpass filter components are shunting signal to ground.

9. You could unplug and clean Ant Relay contacts. Normal failure here is bad contacts which could cause weak and/or intermittent signal with coax connected to rear chassis so-239. Would not expect bad contacts at Ant Relay RL-1 to shunt signal to ground and affect any signal applied at TP-1.

ACTION: Unplug Connector 3 and re-apply coax signal to TP-1 and report back.

31749. Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-08 16:03:44 UTC
From: Terry Wagoner
Topic: 31735 Message: 31749

Mike/Gordon--I do not want to abandon Joe, but I have exhausted my knowledge/experience with his problem. He does not have the test equipment necessary to use Level diagrams so is using antenna coax to inject signal. He is good downstream of L4/L41 with antenna coax signal applied at VC-1. He is not good with antenna coax signal applied at TP-1. Marker signal is good. I am not sure what the components are after TP-1. They appear to make up a band-pass filter (perhaps broadcast band?) and I cant imagine any of these failing open or shunting signal to ground. Appreciate it if you guys could add to what I have suggested and/or take off and run with this one. 73s Terry

Subject: Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

Joe--If the Marker is "buzzing" the speaker with AF gain wide open I would say that L4 and L41 are ok. On my TS-830 I get about 10 over S-9 on 80, 40, 20 with

driver peaked. Maybe around S9 to 5 over on the higher frequencies. In all cases

I need to turn down the AF gain when Marker is on and Drive is peaked.

1. There are 3 possible failure modes 1. Open signal path 2. Shorted or Shunted signal path 3. Intermittent signal path (doesnt fit your symptoms)

2. We have determined that signal path from Marker to Speaker is good/normal.

3. We have determined that signal path from VC-1 is good/normal (including AGC action?)

4. We have determined that signal injected at TP-1 produces significantly weaker

output. What components and what failure mode are in path from TP-1 to VC-1?

5. L4/L41 share path with Marker and antenna signal and Marker is good therefore L4/L41 are good.

6. When you apply coax signal to TP-1 you say signals are much weaker than when touched to VC-1. As I mentioned the coupling caps and what I believe are band-pass components (probably broadcast band?) are the only components in path from TP-1 to L4/L41. These components typically dont go bad. These components are not in the circuit when you use the Marker.

7. So, is it possible that something is shunting/shorting the signal to ground at TP-1?

8. Can you unplug Connector 3 carefully and then re-apply coax signal to TP-1? If signal comes up to near same as when touched at VC-1 then you know coupling caps and band-pass filter components are all good. The fault then has to be something shunting the signal to ground upstream of TP-1. If signal does not come up, then coupling caps, bandpass filter components are shunting signal to ground.

9. You could unplug and clean Ant Relay contacts. Normal failure here is bad contacts which could cause weak and/or intermittent signal with coax connected to rear chassis so-239. Would not expect bad contacts at Ant Relay RL-1 to shunt

signal to ground and affect any signal applied at TP-1.

ACTION: Unplug Connector 3 and re-apply coax signal to TP-1 and report back.

Subject: Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

Terry:
At 14.175 mhz with the drive peaked, I get an S7 calibrator reading. Quite different than I get 1.9 mhz -- you're correct, it buzzes the speaker. I'll try your other suggestions when I get a chance later on this evening. I probably should think about checking the relay as Dave suggested.

One other thing that may be related, is that when I'm on a strong signal the S-meter fades. In other words, as it is now the strongest signals are around S7 or so... when I tune on them by watching the S meter, after a few seconds the S meter drops off and comes back up and drops off. When I connect the antenna to VC-1 lug the S meter does not fade -- nor does it fade on the calibrator signal.

The coils, L3 and L4, after TP1 on the RF Unit are the 8.83Mhz "traps". There is an adjustment for these in the 830 service manual.

If the Marker signal is good but incoming signals are not then the problem is before the RF Unit or possibly a bad solder connection on the ANT pin. It also could be caused by a bad RF ATTN switch. The Marker signal does not flow through the RF ATTN switch. It also could be a very dirty or bad antenna relay connection.

Joe would need to walk a signal from a generator starting at the SO-239 connector (coax connector on the rear panel) to each point along the path to the RF Unit's "ANT" connection. At some point he will find the signal becomes strong which will tell him the problem is just before that point. A simple signal generator such as a Heathkit IG-102 will do the trick. He doesn't need an expensive signal generator to perform this diagnostic test but he will need a signal generator none the less. The Marker signal is applied directly to the RF Unit, it doesn't flow through the same path as the incoming signal does, from the SO-239, through the antenna relay, the RF ATTN switch, then to the RF Unit.

One more thing. If the Marker signal is strong, S9 or better, then L3 and L4 are more than likely not the source of weak receive signals. If L3 and/or L4 were the source of the problem the Marker signal would be weak just like the incoming signals are.

Ok Mike, like i was thinking.

Thanks.

Hope to meet you on the bands.

(off topic
lots of stations overseas have been comin in,
both on 40 and 20, although we've been havin
a lot of thunderstorm static. if youre in any freq or net,
let me know, if you will. me, i make some calls, and sometimes
ppl answer :P)

cheerio.

Ken;
The idle current should be set @ 60ma per the service manual - Use the bias pot on the rear to set this
and follow the instructions in the service manual.

Mike--I was talking about the components between TP-1 and L4. In addition to coupling caps appears to be a band-pass filter? and I suspect is for broadcast band, but I am not sure. Cant imagine any of these caps or inductors being bad.?

I understand L3 and L4.

Since he replaced L4 and L41 I wanted to make sure they were good. Since L4 and L41 are common path for rf signal and marker signal and he gets strong marker signal (S9 +) I assumed that L4 and L41 replacement was no longer his problem.

He is now injecting signal at TP-1 and the signal is significantly weaker. My logic says either "bandpass filter" components are bad or Pin 3 Ant terminal is grounded? I recommended that he unplug Conn 3 and see if signal now injected at TP-1 is strong.

I agree it looks like problem is at or before Ant terminal. I guess I would have believed likely failure mode at ANT terminal would be open or intermittent and signal injected at TP-1 should still be strong in that case. Terry

Subject: Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

The coils, L3 and L4, after TP1 on the RF Unit are the 8.83Mhz "traps". There is an adjustment for these in the 830 service manual.

If the Marker signal is good but incoming signals are not then the problem is before the RF Unit or possibly a bad solder connection on the ANT pin. It also could be caused by a bad RF ATTN switch. The Marker signal does not flow through the RF ATTN switch. It also could be a very dirty or bad antenna relay connection.

Joe would need to walk a signal from a generator starting at the SO-239 connector (coax connector on the rear panel) to each point along the path to the RF Unit's "ANT" connection. At some point he will find the signal becomes strong which will tell him the problem is just before that point. A simple signal generator such as a Heathkit IG-102 will do the trick. He doesn't need an expensive signal generator to perform this diagnostic test but he will need a signal generator none the less. The Marker signal is applied directly to the RF Unit, it doesn't flow through the same path as the incoming signal does, from the SO-239, through the antenna relay, the RF ATTN switch, then to the RF Unit.

73s
Mike

31755. Re: Instability on one band, 20m, only

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-08 21:18:46 UTC
From: David
Topic: 31720 Message: 31755

After recently changing the final tubes, I had all kinds of poor stability on the lower bands when neutralizing them on ten meters. It included blowing fuses. As soon as I did the neutralization on 20 meters everything worked great on all bands, the current draw went way down, and no more blown fuses.

Think about it

Topic: 31735 Message: 31756

Thanks Mike and Terry...
You guys have given me plenty of time and advice -- I appreciate it very much.
I have a signal generator... an old Eico 324 and a qrpkits signal injector/tracer (http://www.qrpkits.com/tracerinjector.html) which may work also, so I can try what you are suggesting. As far as marker signals go: I get a 20+ db marker signal at 1.900 mhz when adjusting the L41 for a peak, but at 14.175 mhz, the marker signal is only S7.

What ever took out the L41 (remember I said the secondary winding was open -- a inch of the wire was missing, but the windings were intact and not burnt), probably also took out something else, which is continuing to be a problem. Before rewinding the L41, I had virtually no signal -- after replacing L41, the signal came back and is now weak. Only when I put the antenna input at VC-1 does the signal come up to sounding like a properly operating receiver.

Wish me luck and thanks again.

73,
WW8X
Joe

[Non-text portions of this message have been removed]

31757. Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-08 21:51:26 UTC
From: n6wk@n6wk.com
Topic: 31735 Message: 31757

Joe,
Insert a 14.175 signal at the center of the SO-239 and take a reading on
the S-meter. then insert the same signal at TP-1 on the RF board and
again look at the S-meter. tell me what readings you get.
they should be virtually identical.
Once we have that info, we can move on

Gordon

Gordon,
The signal from the generator (Eico 324 at 14.173 mhz (that's as close as I
can get it reading from a BK frequency counter) are:
SO239 is slightly less than S7
TP-1 is slightly less than S7
TC-1 is 20 over S9
TP-2 is 20 over S9

WW8X

Gordon,
The signal from the generator (Eico 324 at 14.173 mhz (that's as close as I
can get it reading from a BK frequency counter) are:
SO239 is slightly less than S7
TP-1 is slightly less than S7
TC-1 is 20 over S9
TP-2 is 20 over S9

WW8X

Correct Terry...
The signal from the generator (Eico 324 at 14.173 mhz (that's as close as I
can get it reading from a BK frequency counter) are:
SO239 is slightly less than S7
TP-1 is slightly less than S7
VC-1 is 20 over S9
TP-2 is 20 over S9
Thanks for the catch.

31761. Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-09 00:38:27 UTC
From: n6wk@n6wk.com
Topic: 31735 Message: 31761

Joe,
Do you mean TC1 or VC1 ?
Also, did you mean TP2 which is the RIF terminal?

Gordon

31762. Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-09 00:39:43 UTC
From: n6wk@n6wk.com
Topic: 31735 Message: 31762

Ok, in that case, either there is a problem with L-41 or L4 needs to be
adjusted

Gordon

31763. Re: TS520se Tx power

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-09 00:44:15 UTC
From: Bill
Topic: 31719 Message: 31763

Hi Dave,

Maybe shining a different color of light on this from a different angle will help. The ALC is to prevent the final amplifier from being overdriven and causing distortion, splatter, all manner of grief. The ALC only 'engages' *if* the finals experience any overdriving condition. I think that part of the picture has been pretty well said several times.

If we reduce the power by reducing the 'carrier' in CW or the mic gain in SSB then we are NOT EVER (read as NEVER) going to overdrive the finals. If we reduce the power by using the nine volt battery trick we will have forced the ALC to reduce the transmitter power and again...the finals will never be overdriven. When we have reduced the ouput power by any substantial amount we can forget all about the ALC level.

On the rare occasions I use SSB on my Kenwood and I want to use "full" power, I adjust the mic gain up until I just get some ALC on the peaks and THEN I back it off until that just stops. I am still close enough to full power that you can't tell the difference from your QTH even with lab measurement gear. You probably couldn't measure the difference even from across the street. The reason to just 'tickle' the AGC is to know you are at the transmitter's clean operating limit. Once you know that the meter isn't needed.

I hope this helps a little.

73,

Bill KU8H

31764. Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-09 00:51:03 UTC
From: Joe Loverti
Topic: 31735 Message: 31764

I got messed up... darn it.
TP-1 is less than S7
TP-2 moves to S3 then drops to S0
TP-4 is 20+
VC-1 is 20+
SO239 is 20+

Sorry about that...
WW8X
Joe

31765. Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-09 00:53:31 UTC
From: Joe Loverti
Topic: 31735 Message: 31765

I truly am sorry... still messed it up.
TP-1 is less than S7
TP-2 moves to S3 then drops to S0
TP-4 is 20+
VC-1 is 20+
SO239 is less than S7
One of those nights :?(
WW8X
Joe

Topic: 31735 Message: 31766

No problem Joe,
Been there and Done that LOL

Ok, if TP1 is S7 yet VC1 is 20 over, the loss is in L41, L4 or maybe
even L3. look at the schematic and you can easily follow the circuit.
It could also be one of the caps in that associated circuit, such as C1,
C3 or C4 but I doubt that.
I am thinking it is L4 , L3 or L41 has the issue. The part that puzzles
me is that the marker signal seems to be good.
Are all bands low? Maybe you need to do the Antenna and RFcoil
adjustments for all bands.

Gordon

31767. Re: [TS-520_820_530_830] TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-09 01:27:41 UTC
From: n6wk@n6wk.com
Topic: 31735 Message: 31767

Joe,
one pother question, You did wind L41 correctly as far as primary and
secondary pins on the coil... correct?
The primary also is wound on the bottom 1/3 of the bobbin while the
secondary is wound on the top 2/3 of the bobbin

Gordon

>
>
>
>Hi Dave,
>
>Maybe shining a different color of light on this from a different angle will help. The ALC is to prevent the final amplifier from being overdriven and causing distortion, splatter, all manner of grief. The ALC only 'engages' *if* the finals experience any overdriving condition. I think that part of the picture has been pretty well said several times.
>
>If we reduce the power by reducing the 'carrier' in CW or the mic gain in SSB then we are NOT EVER (read as NEVER) going to overdrive the finals. If we reduce the power by using the nine volt battery trick we will have forced the ALC to reduce the transmitter power and again...the finals will never be overdriven. When we have reduced the ouput power by any substantial amount we can forget all about the ALC level.
>
>On the rare occasions I use SSB on my Kenwood and I want to use "full" power, I adjust the mic gain up until I just get some ALC on the peaks and THEN I back it off until that just stops. I am still close enough to full power that you can't tell the difference from your QTH even with lab measurement gear. You probably couldn't measure the difference even from across the street. The reason to just 'tickle' the AGC is to know you are at the transmitter's clean operating limit. Once you know that the meter isn't needed.

Topic: 31735 Message: 31769

Gordon--Good marker thru me off as well. Since L4/L41 are common path for marker and RF signals.

How about injecting signal at Diode D1 by Marker pin. It is near TP2 and cathode end of diode is accessible. If signal is 20+ injecting here it cant be L4/L41--Terry

31771. Re: [TS-520_820_530_830] Re: TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-09 02:47:36 UTC
From: Joe Loverti
Topic: 31735 Message: 31771

The results of the signal injection seem to vary somewhat... maybe it's that old generator? Anyway, I also took a reading with the signal injected at D1 as suggested by Terry. Here's my readings:
SO239 = S7
TP-1 = S7
VC-1 = 20+
TP-4 = 15+
TP-2 = S3
D1 = S0 to S3
Connecting an antenna to VC-1 makes the receiver come alive like it was new!

As to the L41: I wound the primary on the lower third and the secondary on the upper two thirds. There was some overlap of windings but not too much. I noticed when I was done with the windings the ends of the wires crisscrossed over each other. Like the beginning and end of the primary and the beginning and end of the secondary crossed before going to their respective pins... I wondered about that at the time. Improper technique?

I don't have a problem with redoing it. The second time should be easier since I know how to properly install the band switch shaft and now not intimidated by tearing out the RF board as I was the first time. I just want to get this baby cooking once again. It really is a beautiful rig!

Based on what you guys have said... looks like I need redo the L41.

Thanks for your time...
Regards,
WW8X
Joe

Joe, The beginning and ending of the windings do overlap each other (crisscross). that is normal
I have NOT finished my video, but perhaps I should forward what I have to you to see if it gives you any clues. the problem is, I wound one backwards in the video and have not had time to redo that part. However, it clearly shows which pins are for primary and secondary
IO wonder, what part of VC-1 are you touching?

Gordon

31773. Re: [TS-520_820_530_830] Re: TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-09 04:47:02 UTC
From: Joe Loverti
Topic: 31735 Message: 31773

Gordon: I'm touching one of the lugs at the top of VC-1 -- there are two, each produces the same results. I didn't realize there could a backward winding.... I never paid any attention to that... I just wrapped and counted them as I went along. I've done enough damage for one day... :-)
73,
WW8X
Joe

31774. Re: [TS-520_820_530_830] Re: TS520se Tx power

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-09 09:56:14 UTC
From: Dave
Topic: 31719 Message: 31774

Thanks Mike and Bill. Agreed.
My original question should have been more specific.

SSB vocal QRP
Earlier posts from K0ZL's time onwards, advised to use the 9V circuit rather than mic gain but recent posts advise mic gain.
Has opinion has changed? and if so, the reason.

Thanks
Dave f4eyk

31775. Re: TS-830S closing in on low receive problem

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Topic: 31735 Message: 31775

Joe/Gordon--Touching the fixed plate connection point on VC-1 is an old trick I learned 40+ years ago working on old 5 tube am radios. When you removed the back you lost the loop antenna so you could use your body as an antenna and touch the 365 uuf variable tuning cap to check front end of receiver--a poor mans signal generator!

With weak results with signal injected at TP-1 and Marker input looks like L41 is the culprit. I just wanted to make sure there wasnt something shunting signal to ground. I would take a hard look at soldering at L4 and L41 before removing them to ensure no bridged foils or shorts to ground. 73s Terry

31776. VBT Oscillator Adjust w/o VBT-1 Test Jig

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Chris Parnell and others;

Chris I forgot to mention that when using the alternate method to perform Step 23 on page 38 of TS-830 service manual that the accepted waveform is mis-labled. You want a sinusoidal pattern that cleanly crosses at zero. You adjust to obtain a null at zero crossing. The pattern marked as "A-OK" is not correct. The pattern marked "NG" is what you want.

There is another method that Kenwood describes in Service Bulletin No. 873 (15-7-1983) that employs 2 audio generators (essentially a 2-tone test). The test method as described will work, but the adjustment steps will not as they are for a TS-930 and not a TS-830. Service Bulletin N0. 873 is readily available on web.

I think for average owner the method described by Richard Measures in the Survival Guide works well. Just takes multiple adjustments to arrive a best filter overlay.

As point of reference I have 2 full filtered rigs and my as left setting of VBT oscillator is 8375.121 and 8375.071. I dont know if being in + direction is norm or not. I do know that just setting to 8375.00 does not optimize VBT.

Chris-I would be curious to know what method(s) you use and your experience/results. 73s Terry_ K9TW

Terry/Gordon:
I've worked on a number of those venerable AA5's myself. These transceiver's make those look like child's play!

Attached is a diagram of what I did to rewind the L41. I rewound it with the primary on the bottom of the spindle and the secondary on the upper part. There was some overlap of windings, but not excessive. The ends were crisscrossed however -- and at the time thought it may be a problem. Gordon says its normal for those to crisscross.

Joe--I have never rewound one and wont be hurt if dont get the opportunity! I would certainly go by what Gordon is doing because he has seen the factory winding during autopsy and has had multiple operational successes rewinding these micro xfmrs.

When you remove it would be good to measure resistance of primary and secondary windings at the pins before you remove metal cover. Assumes you can read low ohms reasonably accurately? This will tell if your windings are open circuited. I doubt short circuited as you havent had any source of high current to do that. I would think open circuit or high resistance connection from winding to pins would be more likely reason for weak signal versus inappropriate degree of coupling between the two windings?

Maybe Gordon can give you the as left winding resistances you should have or advise if it is feasible to read them? I recently bought an ESR meter to test capacitors and it has low ohms range of .01 to 99 ohms. With most DMM s best you could do is check continuity and not be able to read low ohms sufficiently accurately. In old days you would use a Wheatstone or Kelvin bridge. Not many hams have those laying around.

I always like to understand failure if I can so I dont repeat same sins! Anxious to hear what you find.
Terry

Hi Dave,

My opinion hasn't changed. My opinion is that the 9 volts applied to the ALC OR using the controls already on the radio will work. I only recently even heard about forcing the ALC. When I tried it, sure enough... it worked. And I noticed I had an extra nine volt battery, some wires, and a pot to *put* somewhere. That's why I choose to use the controls that are already in the radio. If you already have a neat enclosure that contains your battery and pot and a wiring harness all made up then using it will work just as well as the controls that Kenwood supplied built-in to the radio.

It's all good.

73,

Bill KU8H

I think I'm missing something.

Why do I need to do this? It's been working fine since
that day I got it many many years ago.

Hello John,

I assume you are referring to the power reduction 9 volt battery and pot circuit. Unless you are considering running low power on sideband then you don't need to do any of this.

However, if you are considering running low power sideband then before using the circuit I recommend learning how the circuit works to control power output. It's a simple way to control power output but it can, if one is not familiar with how the circuit works, be confusing. Knowing and understanding when and how ALC is produced, how ALC controls the IF amplifier gain will make it much easier to understand how this simple 9 volt battery and pot circuit connected to the Remote ALC connection works.

Hi amigos !
A very annoying problem is affecting my old TS820S ...
Here is how it happens... a local amateur is on 7045 kHz, with a strong signal...
I am listening to a far away station on 7060, his signal is an S7, but the audio from the 7060 station has as a background the audio from the station on 7045 kHz...
And NO, the Noise Limiter is NOT ON !!!
Same thing happens when I try to work QRP stations on 14060 and the ARRL CW drill is on around 14047... the ARRL practice is superimposed atop the weak QRP station !!!
Also, and as an additional problem, the digital readout is stuch reading 9.000. and the the last digits moves from 0 to 9 as I tune the transceiver !!!

Any ideas or suggestions on how to repair - fix both problems will be much appreciated...
BTW, following a recent thread, I can make the TS820-S go down to 500 milliWatts very easily ... transforming it into a terribly inefficient QRP rig !!!

If you have two units doing the same thing are you sure you do not have antenna problem?

Everyone that works on equipment like this needs a simple signal generator like a Heathkit SG-8 or IG-102.

Then if you are not a scope user a Heathkit IT-12 signal tracer can be a help.

All three of these item sell cheaply on eBay. It might also be nice to have a real VTVM.

Hi Arnie,

Yes... nobody said anything about about the wonderful efficiency of one of these transmitters operating QRP! That's good because the efficiency is awful compared to even a purpose built tube-final QRP TX.

Good luck with your 820s.

73,

Bill KU8H

31790. Re: [TS-520_820_530_830] VBT Oscillator Adjust w/o VBT-1 Test Jig

Hi Terry,

Will let you know when I get around to doing the VBT, what my findings are.

Thanks
Chris, ZL1CDP

Hi Terry,

I did get the following suggestion, but it didn't make any difference on my set.

Hi,

i found myself exactly in the same situation: simply inject 50 mV instead of 10 mV as stated in the service manual and you will get enough meter to align it. At the end you are balancing proc on vs. proc off positions.

73's Joe.

All I see is as per my original post... (unless I have misunderstood the logic behind Joe's post).

This is where my 830 (or me) gets stuck..
Every step works until I get to the point where I turn the Proc ON and
adjust L27 for the same reading as where the PROC is off.
On adjusting L27 with the PROC ON I get no movement on the meter at this
point, and therefore cannot obtain the same ALC maximum reading.

So, even if I inject 50mV (instead of the stated 10mV in the service manual), I get "full scale deflection (in fact whacking over) with no Proc engaged" and with 50mV with Proc on, I can adjust L27 to get it to full "on-scale" meter of ALC, but my understanding according to the instructions, is that with 10mV injection you should be able to align Proc on and Proc OFF to both read the edge of the ALC scale.

So, I would love to hear from anyone as to what could be going astray here.

Cheers
Chris, ZL1CDP

>
> I have not performed this step. I am stuck on Step 31 ALC adjust. I can do Step 1 and adjust VR6 for exact zero but cant do Step 2 as written with mic gain set to max as it pegs my meter hard with 5mv signal injected at mic connector. I have to reduce mic gain to get max full scale reading and then reduce it further to see 5 watt power reduction. I have found that some of these steps cant be performed as written. Because of this and test equipment limitations many(ok-some)of the fellows just perform the Sect 6 maintenance adjustments and a few select Service Manual steps. Setting voltage regulators, carrier adjustments, are all commonly done. Hard to do PLL BPA if you dont have good sweep generator and good scope. Also, spectrum analyzer is beyond reach for many. I watched an experienced kenwood tech adjust VBT oscillator by simply adjusting TC-2 to exactly 8375.0 khz. That is ok if it was grossly out, but real adjustment is described on Pg 38 with two methods that are more complex. I have used these steps and my VBT oscillator in 2 different

830s is set from about 50 to 100hz higher than 8375.00 to align the filter passband windows.

Chris,

Have you tried lowering the signal level with the processor ON to the point where the indication just starts to show then perform the adjustment? You may have to alternate the processor ON and OFF settings while varying the signal level when making the adjustment so the ON and OFF settings are equal.

Just my 2 cents worth.

31797. Looking for an AT-200

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-10 22:37:48 UTC
From: Jeramy Ross
Topic: 31797 Message: 31797

Hello all,

I am looking for a good AT-200. I have a Ten-Tec model 228
antenna tuner (w/ documentation and original box) to trade with a
willing party. The 228 is in good condition, and works great.
However, now that I have returned to having a hybrid based station
after a fling with Ten-Tec gear, I would like to have the AT-200 which
matches my TS-520S and TS-820S gear.

Thank you in advance and 73,
Jeramy W5XTL

31798. Output impedance matching network

Topic: 31798 Message: 31798

Hi all,

I have a question regarding the handling of the output impedance matching network of the TS830 or any similar rig.

I often tune my rig to 14.070 for PSK operation. Then I move down by 15 KHz to 14.055 for QRS CW. Of course I would retune Drive, Plate and Load in that case. Is that correct or am I too cautious? If so, what would be a safe distance from the tuned frequency where I can move the VFO but not re-tune the output network. 5KHz? 2.5KHz?

Jan, I was always of the opinion it never hurts to peak the drive and dip the plate, doesn't take but a second. Just insert a little carrier and tune it.

Dave,

yup, that is what I do right now.

In a voice spectrum we'd have 2.7 KHz coming through the filter so my assumption would be that moving 2.7 KHz up or down with a CW carrier should not hurt.

Just wondering if all OMs here always re-align with every frequency change.

My TS520 stayted in tune well enough over most bands except 80 and 10M where I really did a big QSY like 100 kHz !

If your CW key down plate current varied much more than 5 or 10 mA with a little QSY like that, you probably have some serious antenna issues !!!!!

Subject: [TS-520_820_530_830] Output impedance matching network

Hi all,

I have a question regarding the handling of the output impedance matching network of the TS830 or any similar rig.

I often tune my rig to 14.070 for PSK operation. Then I move down by 15 KHz to 14.055 for QRS CW. Of course I would retune Drive, Plate and Load in that case. Is that correct or am I too cautious? If so, what would be a safe distance from the tuned frequency where I can move the VFO but not re-tune the output network. 5KHz? 2.5KHz?

Topic: 31798 Message: 31803

I don't re-tune if the frequency change is small, and 20KHz or so at 14 megs is small.

20KHz at 3.5 megs represents a larger percentage and may benefit from a bit of peaking.

In any case, it can't hurt as long as you don't whack full carrier just to tune up - in BPSK mode using DigiPan I select MODE and TUNE in the software and advance the mic gain just enough to see a deflection, which is enough to peak the rig's DRIVE whilst watching the IP, and dip the PLATE. A bit more power and you can adjust the LOAD. Very quick to do.

Jan
that depends how far I have to move up or down the band
and what the meter tells me.

Stan, some where in the 3 million serial number, Kenwood switched to the GOLD series. It has the lettering in Gold under the VFO. There are rumors that all Gold versions came with all the Filters installed, but that is a Myth. The optional filters were added to the Golds as a promotion for a short time. Many Golds did NOT come with all 4 filters installed from the factory.

What is the serial n8umber of the new rig?

73,
Gordon

Hi gang, I hope someone can answer this and guide me through the procedure. I have an Audio Comm boomset that was made for a Ten Tec omni 5. If I remember correctly (and that is a stretch) My 530 s and 820 s use a dynamic mic? I believe the audio comm is electret. I only used it a few times when I had to sell my omni 5. The recieve audio is very nice and it sounds great to my ears on the Kenwoods. I always got good transmit audio reports. Is there (and I'm pretty sure there is) a way to get this boomset to work on my Kenwoods? I sure would like to. I'd even be willing to send it to one of you and have you do it for me.In other words I'm willing to pay to have someone try. My eyes and hands aren't good for much anymore. Thanks Richard KM5WX

Not true Gordon. My TS-830S is Serial # 1081195 and it has the lettering in gold under the VFO. I am the original owner. Kenwood only used the silver lettering in roughly the first year of production and then switched over to the gold lettering under the VFO. As has been reported for years here on the Group, the "Gold" edition, "Gold" line, etc. has been a long running myth of added features/functions/etc. The marketeers added the optional filters at the tail end of the TS-830S life cycle to move the last of them out of the warehouse and out of the dealer's inventory and used the advertising tag "Gold Edition".

Well, Don't know what to say Pete as I have had quite a few Silver
editions through here that were in the 2 million and under serials.
They also had the -5 little Murita filter instead of the -12.
I also had a 3.1 million here that had the Silver lettering.
Maybe you have the Only 1.8 million serial gold Version in existence.
Maybe we should get everyone to post their serial and what version they
have on the group.
I agree, the Gold myth is exactly that.. A myth, regarding them coming
with all 4 filters, as I said before.

The lettering on mine is faintly gold colored, but it has no additional filters. I just completed replacing the back panel, the original of which was badly corroded. Apparently the previous owner stored the radio for a while in a high humidity area. I got the new one from Bob Mansker. I love buying items from him because they are always in great (near new) condition. Things here are good, but I long for the days of flying the smiley faced PSA airplanes out of Lindbergh Field. I need to get out there for a visit and make some stops at places like Rubio's, In and Out Burger, Fat Burger, El Torrito's and all the rest of the fun places. We're supposed to get storms later tonight but today the weather was like San Diego. Clear and 70 degrees. I guess that's it for now. Take care, glad to hear you are well.73,Butch KØPSA

31813. Re: TS 830S (production dates)

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-12 07:08:35 UTC
From: g4fui
Topic: 23875 Message: 31813

Guys,

My TS-830S has serial number 7070114 and according to the date codes on the chips inside (usually a pretty good indication of manufacturing date) it was made in 1986.

This was an EBay purchase, so I have no idea of the provenance of this particular unit.

However I don't think this was one of the enhanced "Gold" units, as I have had to fit the CW filter myself.

I remember being quite surprised at the late date of the unit - a testament to the popularity of the model, I suppose, and note that mine is "Kenwood" branded. The company used the "Trio" brand name in Europe through the early 1980s, I'm not sure exactly when that was dropped and they switched to "Kenwood" as was used continuously in the N.American market.

On the subject of the Kenwood serial numbers versus date of manufacture, I think I read somewhere that there is a rough relationship.

Serials in the "1 million" range made in 1980
Serials in the "2 million" range made in 1981

etc.

This seems to be borne out in my own collection. Comparing serial number with the "component date code" method of dating produces the following :-

TS-180S s/n 9xxxxx made in early 1979
TS-130S s/n 1xxxxxx made in 1980
TS-530S s/n 2xxxxxx made in 1981
TS-830S s/n 7xxxxxx made in 1986

Unfortunately, I haven't found either a serial number or credible date code on my old TS-520!

Unlike the well-known Yaesu numbering/dating scheme I suspect the Trio/Kenwood system is rather less precise, but as you can see the relationship appears to be roughly correct.

Hope this is of interest

It transmits into an ATU anyway so it's always +- 50 Ohm towards the Antenna.

That however is exactly my point. Plate current varies next to nothing with a QSY like that so it might be OK to leave the network in its tuned state.

31816. RE: Output impedance matching network

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-12 17:46:35 UTC
From: Bill Cromwell
Topic: 31798 Message: 31816

Hi,

I learned form the old timers that the last step in a tuneup is dipping the plate. If I QSY about 10 kc or more I redip the plate. 20 to 25 kc maybe checkup on the drive, too. In my actual operation I don't pay as much attention to the actual frequency as I do to band and sub-band edges. So most of the time if I think I have moved about that far I do the deed. Bottom of the sub-band, Middle of the sub-band, Top of the sub-band sort of thing.

I have a log sheet of where my antenna matcher is set on each band. Once in a while I do a reality check on that. When I want to redip or do the whole tuning process I select the dummy load for the transmitter and do it off-air. When I put the antenna back on it's still good (and I've verified that).

The reason to redip the plate is to maintain the harmonic suppression. The plate dip is the most important part of that (according to the ancients). I haven't got into any trouble doing it that way whether I'm using a Kenwood, a Johnson Ranger, a DX-100, or whatever. They're all the same. They only *look* different.

73,

Bill KU8H

The PLATE and LOAD controls are part of the PI Network circuit. As the PLATE control is adjust for a dip in IP current, the input to the PI Network become a closer match to the high impedance of the final amplifier. As the LOAD control is adjusted, the output of the PI Network become more of a match to the load (antenna or dummy load) presented to the PI Networks' output. When these controls are adjusted properly the PI Network is said to be "resonant" at the operating frequency and maximum power is transferred from the final amplifier to the load (antenna or dummy load). Some view the PI Network as an "antenna" tuner which there are similarities.

If the frequency changes, so does the resonance of the PI Network. If the frequency change is only a few Khz or so, a few means 2 or 5Khz, then no adjustment would be needed.

Personally, a change of 15Khz is a significant change that, in my opinion, would require a touch up/adjustment of the the DRIVE, PLATE, and LOAD controls.

If the transmitter is tuned into a load the PI Network cannot match (LOAD control) then the meter indications will be false or misleading. IP current will be much higher and RF output will "appear" to be higher than normal. To eliminate this problem a tuner will be required between the transmitter and the antenna or the antenna will have to be "pruned" to resonant on the operating frequency for lowest SWR. SWR can cause misleading RF output indications such as those hams who say their TS-520 produces "150 watts" output. The limits of the PI Network are typically between 30 ohms or so on the low end (LOAD control set fully CCW) and 125 ohms or so on the high end (LOAD control set fully CW).

The PLATE control does NOT change the high impedance of the final tubes nor does the LOAD control change the impedance presented to the PI Network's output. The 2 controls simply present as close of a match as possible to each side at the operating frequency.

The same applies to a tuner. A tuner does NOT change the load impedance presented to the tuner's input and output but rather, when adjusted properly, provides as close of an impedance match to the impedance presented to the tuner's input and output.

The Pi Network final was developed to be able to use a coax fed dipole antenna without an antenna tuner. In those conditions the Pi Network is the antenna tuner.

Prior to the Pi Network output transmitters used some form of link coupling. In those days antenna tuners were devices to connect to balanced lines.

The antenna tuner we know today did not come into used until the conversion od passband solid state finals.

In the early days Heath made a simple L Network tuner to us with the AT-1. They did not produce another tuner until the days of the SB-104. The transmitters preceding the SB-104 all had Pi Network finals.

If you only move 5 or 10 KC you don't have to retune the Pi Network. When fully loaded you don't get the sharp dip.

31820. Re: generator for ts-520s

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-12 18:25:50 UTC
From: w5rkl
Topic: 31818 Message: 31820

The TS-520S has a AC power rating of 280 watts at full output.

Let's assume you will be using the following items and those items will have the power consumption as follows:

2 x 60 watt lights (120 watts total)
1 x 45 watts computer for logging
1 x TS-520S at 280 watts

Therefore, the power consumption and demand placed on the generator will be

120 + 45 + 280 = 445 watts

Whether your computer, if used, consumes 45 watts or not, I used this as a figure in my example to show how power adds.

Having said all that, your total power consumption may be different. Therefore you will have to determine the maximum power consumption at any one time based on the individual items plugged into the generator's AC output.

I recommend maintaining a safety margin. Just because, for example, a generator has a constant 1KW power capability, doesn't mean you should have items totaling 1KW plugged into the generator. If, for example, your generator has a constant 1KW power rating, I would not exceed 800 watts.

Topic: 31798 Message: 31821

PI Networks have been used prior to 1960. For example, Heathkit's DX-100 has a coaxial PI Network that had an impedance matching range from 50 ohms to 600 ohms. This was changed in the DX-100B to a much smaller and limited impedance range of 50 to 72 ohms. The Heathkit Apache TX-1 (1958) along with the Marauder HX-10 (1962) also contained a PI Network.

The KnightKit T-60 (1962) used a PI Network. The PLATE and load capacitor both had 2 sections with a shorting band switch wafer as part of the PI Network. Depending on the band selected by the band switch the band switch wafer would short any undesired PI Network tank coil taps.

The Collins KWM2 (1963) also used a PI Network. The band switch wafer selected the desired PI Network tank coil tap instead of shorting the undesired PI Network tank coil taps.

You are correct that many older transmitter final amplifier used link coupling. In many cases link coupling provided a much wider range of impedance matching than the more limited PI Network did.

Regardless of the type of PI Network used, the end result was the same, adjust the output network to resonance for maximum RF transfer from the final amplifier to the load presented to the transmitter.

Mikes calcs are right on. In addition to capacity I would be a little concerned about the output quality and voltage regulation. I know hams use generators for field day all the time. I think if I was to do that I would install a surge protector between the generator output and my rig and lap top. Maybe a homebrew 120volt box with some MOVs? I am probably just a worrier, but I would hate to have a spike damage my electronics. Maybe not a problem with newer generators?

I have a 5kw 10 hp Dewalt that I use to power my drinking well, fridge etc when we lose power. I have never scoped or monitored the output, but do not use it to power my rig, computer or TV. I know it doesnt have greatest voltage regulation because lites dim when other loads take a bite. There is a warning label on it on it about not using to power electronics, but I suppose manufacturers do that to cover their butts?

I was always under the (mis?)impression that the cheaper generators
used modified sine/sqquare wave outputs, while the ones for electronic devices
needed to be true sine wave outputs. Can anyone
shed any light on this subject?
Thanks

Topic: 31798 Message: 31824

Mike is right the Pi-network has been around long time. I think it was introduced with the advent of coax feedline which made it easier to get feedline into the shack. I am getting old as I actually remember Link Coupling and using 600 ohm homebrew ladder line for multiband antenna.

As Mike states the pi-network matches the impedance of the tube plate to the antenna and at resonance you get maximum power transfer. It doesnt change the impedance of either load. It also does offer better harmonic suppression and of course provides "flywheel" effect for CW operation.

It might help you visualize it if you redraw it from its traditional PI configuration. Draw it as a parallel resonant circuit. On your paper draw a coil vertically oriented. Across that coil draw 2 variable capacitors connected at the center. The top capacitor is your Plate capacitor and the bottom capacitor is your Load capacitor. Bring a lead off the top and label it A. Bring a lead off the center tapped capacitors and label it B. Draw a line off the bottom and label it C. I draw a variable resistor across A-B and label it Rtube or Rplate. I draw a variable resistor across B-C and label it Rant.

Now it is easier to see what you are doing when you adjust either resistor. If you adjust either resistor (same as antenna presenting different resistance when moving in frequency) then you have to adjust the capacitors. Anytime you adjust either capacitor you have to adjust the other to restore balance in the parallel resonant circuit.

This helped me visualize what is going on. I wish Kenwood would have placed Plate cap on left and Load cap on the right side of front panel then it would look more like PI networks drawn in the texts and schematics. Just for us dummies! 73s Terry K9TW

Here's a tip from experience:
You don't say that you will be using an amplifier, but let's suppose for the moment you are.

The 4KVA generator is chugging along nicely when you suddenly key up:
The RPM slows down, the govenors compensate and the electrical regulation within the generator also compensate for the voltage drop. The effect as far as you are concerned is a lowering of the voltage for amoment until things stabilise.

When you let go of the mic, the opposite happens:
the RPM overshoots slightly before the govenors can adjust, and the voltage will increase a bit before the regulation takes hold. This voltage surge might be problematic, but we got around it nicely by connecting a 2KW heater to the generator permanently - this had the effect of loading the generator and the surges deminished to barely noticable. This additional resistive load will also absorb to a good degree any spikes the generator may generate.

In brief:
Get a bigger generator than you need and load it down to perhaps half of its capacity with resistive loads - this could be the above mentioned heater or a collection of lamps. Ensure you have enough spare capacity left to power the rig!

A well-loaded generator will output a more stable and spike-free waveform, in the cases I have experienced. use a 4 or 5 KVA generator - you will put a bit more fuel in the thing, but thats better than damaging a radio.

Hello Stan,
Here is what I learned since acquiring my radio last summer.

The Kenwood TS-830S lettering below the VFO knob is gold instead of silver. The gold version was to have the optional filters installed from the factory while the silver did not have the filters installed.
Depending on the production run the WARC bands may or may not have been enabled although they were designed into the radio.

The gold editions being sold used may not have the filters installed if the seller decided to earn a bit extra and remove them and sell them separately and sell the gold as being something special when in fact it is now equal to a silver (no filters).

I tend to agree with Martin. I was able to finally find the original owner of my radio, a Gold edition, which was date coded via component date codes to 1986 when the original purchase was made for $879.00. S/N 7090031

Hopes this helps.

Topic: 31829 Message: 31829

With all the discussion about the TS-830S Gold/Silver/date of manufacture I was wondering ...
Does any one know or have a good guestamation of the quantity of each of the models that were manufactured and sold
For example X number of TS-520S
TS-530S
TS-830S
I know I missed a few models.
Just a thought. Not to create a big mess.

I've gotten an SP-70 that is missing that little metal bracket that serves as the rear foot, but also used to hang the speaker from the wall. They look the same as used on the SP-520 and, I'm sure, others.
Does anyone have a spare?
Thanks,
Dave

Hello Peter,

What difference in frequency between transmit and receive?

This problem could possibly be an alignment issue which is covered in the 830 service manual available at Gordon's website

www.n6wk.com/kenwood/

HI Mike,

Thanks for the reply, here is the problems as I am told.

If he wants to work, lets say 14.267.5, he has to tune the radio to 14.267.4, then when he transmits the display changes 14.267.3. Hope this does not confuse you HI HI

From: pmarkavage@juno.com
Topic: 23875 Message: 31836

I've had three here over the years including my original one I mentioned in the previous post. The other two had serial numbers 1912243 and 20101xx ("xx" don't remember the last two digits). Both of these also had gold labels. Actually to clarify, Kenwood called it a 830S "badge" or 830S "name plate". To further clarify, all three of these units were TS-830S (K) which meant they were sold directly in the U. S., and came wired for 120V AC (brown AC cord hard-wired into the unit but was 220 volt modifiable). If you can believe Kenwood's documentation, the original silver badge was part number B43-0643-04 and it was used on the TS-830S (K)(W)(X) models and was called out on the parts list for issue 1 of the TS-830S/M service manual, B51-0916-00 dated 1980.

I also have two TS-830S product brochures here, dated July 1980 and February 1981. Both show the silver badge. A July 1981 product brochure now shows the gold badge and the service manual was updated to B51-0916-10, and the parts list now shows the gold badge with part number B43-0656-04. This same part number also appears in the last issue of the TS-830S service manual B51-0916-20, dated 1984.

The TS-830M(W) used the same badge, B43-0649-04, throughout it's life cycle. Note, (W) means 220/240V AC selectable and the 830 came with a 12 pin connector mounted on the rear panel.

One item up in the air: TS-830S(T) was also 220/240V AC selectable and came with a 12 pin connector. Throughout its life cycle it came with a different badge. It's part number is B43-0654-04. I have no clue why, what it said, or what color it is.

It's also seems obvious that Kenwood's serial number branding did not correlate well with actual manufacturing dates or when the final product was actually released for sale.

Pete,
That is quite a bit of information. Thank you for your post. I for one like to know more about these really great radios. I only have mine about a year and it quickly became the primary rig in my shack due to the fine RX compared to my FT-101ZD-MKII. I like the Yaesu, and use it quite often, but prefer the better RX on the TS-830S. Then my comparison is really 2 different classes of radios.

73,

Bill

I've had three here over the years including my original one I mentioned

in the previous post. The other two had serial numbers 1912243 and

20101xx ("xx" don't remember the last two digits). Both of these also had

gold labels. Actually to clarify, Kenwood called it a 830S "badge" or

830S "name plate". To further clarify, all three of these units were

TS-830S (K) which meant they were sold directly in the U. S., and came

wired for 120V AC (brown AC cord hard-wired into the unit but was 220

volt modifiable). If you can believe Kenwood's documentation, the

original silver badge was part number B43-0643-04 and it was used on the

TS-830S (K)(W)(X) models and was called out on the parts list for issue 1

of the TS-830S/M service manual, B51-0916-00 dated 1980.

I also have two TS-830S product brochures here, dated July 1980 and

February 1981. Both show the silver badge. A July 1981 product brochure

now shows the gold badge and the service manual was updated to

B51-0916-10, and the parts list now shows the gold badge with part number

B43-0656-04. This same part number also appears in the last issue of the TS-830S service manual B51-0916-20, dated 1984.

The TS-830M(W) used the same badge, B43-0649-04, throughout it's life cycle. Note, (W) means 220/240V AC selectable and the 830 came with a 12 pin connector mounted on the rear panel.

One item up in the air: TS-830S(T) was also 220/240V AC selectable and came with a 12 pin connector. Throughout its life cycle it came with a different badge. It's part number is B43-0654-04. I have no clue why, what it said, or what color it is.

It's also seems obvious that Kenwood's serial number branding did not correlate well with actual manufacturing dates or when the final product was actually released for sale.

31843. using CW filters on digital modes

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-13 18:18:03 UTC

Topic: 31843 Message: 31843

Hi

I am trying to figure out if there is a work around for using the 400 khz CW filters when working the digital modes using AFSK like PSK-31 & RTTY.

I suppose the 400 khz filters could replace the SSB filters but then phone reception would be lost leaving the rig would only be good for CW and narrow modes would it not?

Is there something I may have over looked?

Joe--My dad got me started with "galena" crystal set and then bought me an Allied 8 n1 bread board kit. My favorite circuit to build was an am broadcast band transmitter. Moved on to Space Spanner receiver and boy hood buddy had the Ocean Hopper. His brother held a tech ticket and I used to hang around at his house. The days of plug in coils and regenerative receiver were a lot of fun. Of course you had lots of suppliers then with Allied, Lafayette, B&A, Heath and of course World Radio Labs. 73s Terry K9TW

Ok, I am one of those old hams who grew up in late 50's thrilled to have built an Allied Radio Ocean Hopper kit. Are there any of you that may have been a part of this OH generation?

A modification is necessary. See msg 27217. I've sold both my TS-830s now, and have probably lost the info. If you can understand the cct diagrams, I expect you can work out how to make the mod.

Had several command sets but never a Q-5er. How about high Z headphones with cotton covered wire and two pin plugs. If you pulled off one of the pins you couldnt solder it on as the wire was woven cloth braid.

I was lucky to live 90 miles from Chicago and dad would take me to Allied out on Western Ave. I would take all my paper route money and dad would usually help. Probably more than I remember.

I remember getting pretty good at riding the regen control and the bandspread and backing it off just as it went into oscillation. You had to operate those old Allied receivers.

Not sure what this has to do with Kenwood hybrids. Sorry to get carried away.

Thanks Bill. I'm sure we'll go through all of this again in a couple of months. This same issue of "gold edition", gold label, gold whatever for TS-830S has been discussed at least a dozen times or more here. A quick search of the archive posts will turn up a bunch of the same discussions.

They're great rigs but living off 70's and early 80's design methodologies and technology. Component aging and deterioration beyond spec is also a big consideration and concern for any of these rigs.

Allied out on Western Ave...ah yes, I think I might even have an old catalog. BA in Kansas City and Lafayette in New York? maybe. Plenty of places to order just one of a single item if thats what you needed. Heathkit, seems like it was last night I worked on one half the night.

One must take a few moments now and then and remember where we came from, now if I just knew where I was going....

hi Craig,

I would recommend using a full sine wave
UPS to keep the line voltage stable.

APC SmartUPS, Eaton and Liebert are good models.

you may be able to borrow one for field use.

Avoid the modified or stepped square wave
inexpensive ups models.

Many full sine wave models on ebay cheap,
from high rated business sellers without
the battery to save on the shipping.
look for one close to your qth so you save on shipping.

I use an older Liebert UPS for field day, it was
used in pos systems at local supermarkets.

hello there.

the reception on my 520s is a little wrong.

the audio is there, no problem, it just sounds like very thin (almost

no low freqs),

and sometimes it pops and comes back to normal.

maybe any of you guys has had this sort of problem and can point

in the right direction.

ill try to open the thing soon, when i have some patience.

Topic: 31854 Message: 31854

Hi,
On my TS830S when i turn on the calibration control on the MIC knob, the tone is loudest on 14.024.2 then as I turn higher it diminishes and disappears until 14.049.2, etc. Is this the way it is supposed to be or does the freq. readout need to be adjusted?
Thanks and Best 73 from Aaron, WC2C

Hi,

I've see people ask this question before and I wonder why it would be necessary? I understand how a narrow filter helps an operator hear signals on a crowded band but the way I see it the PSK software is quite capable of identifying signals within the passband of the standard filter. Has anyone tried this and tested the difference in performance between a standard filter and a narrow filter on the same signal?

Don't run digital modes in CW! Run them in SSB!

If you use a narrow CW filter you will not see adjacent signals in your
waterfall display. The RTTY and PSK software does not need a narrow filter.

Use the CW filter for CW contests!

I found a few good answers as to why it can't be done, easily at least.
I've had some good experiences with PSK-31 working DX. I just hate it when someone over drives their signal for whatever reason and it takes out signals a kc or two either side of their signal, frequently a DX signal! I use VBT a good bit and I just thought it would be even cooler if I could tighten it down on narrower signals.

Hi (I don't know your name),

I understand your concern but if you have in-band signal directly interfering with the desired signal I think you'll still have the problem even if you do install a narrow filter. I think your original question also summarizes the downside of this change. If you do install a narrow filter you will not be able to use your radio for normal voice communication.

I agree with Bob but I also think that we are all obliged to make sure we make sure our transmission is clean at all times and more so when using these narrow modes. Unfortunately as you have already found not everyone understands or cares about their signal quality and we all pay the price.

See page 21, section 4.7 of the operating manual on how to adjust/check
the dial calibration (simple adjustment if needed).

Some solid state inverters produce a Pseudo Sine Wave.

The thing to use for Field Day is a Honda generator. It produces a near 60HZ
sine wave.

I'm a part of that generation but I did not have an Ocean Hopper.

My first receiver was an original S-38 that had been "RE-KITTED"!

Hi Aaron,

that said, your TS830S behaves like it should, assuming the MODE switch was in the CW W or CW N or USB position.

It makes perfect sense to perform the described alignment once in a while (after warm up!) to ensure accuracy of the displayed frequency.

31865. Re: Output impedance matching network

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-14 10:43:36 UTC
From: pakjan830
Topic: 31798 Message: 31865

Hi Mike,

interesting! Do we know something about the particular impedance range on the load side that the network in the TS830 can handle?

The manual states a 50 Ohm load in section 4.3 but as it handles half wave dipoles, 72 Ohm certainly work too. The manual also says something about a maximum SWR of 2 so by right we should be able to match 25 to 100 Ohm (assuming jX=0)?

The manual is a bit scarce in this area. Say if I tune up into a dummy load of perfect 50 Ohm, then switch over to a real dipole of 72 Ohm impedance, I would need to re-tune, right? Apart from reducing the noise on the air, is there a good reason to tune into the dummy load first? Any best practices?

Topic: 31798 Message: 31867

Hi Jan,

The typical impedance range of the hybrids is like most other tube based final amplifiers, 50 to 75 ohms with a little left over on each end.

After tuning the transmitter into a 50 ohm dummy load or feeding a low SWR resonant antenna with 50 ohm feed line (50 ohm coax), switching to a higher impedance antenna with a higher impedance feed line such as 75 ohms, more than likely will require some "tweaking" of the LOAD control to ensure maximum power transfer. It also would require a check of the PLATE control for any additional dip in IP current.

A change in impedance/load presented to the transmitter, whether capacitance or inductance reactance, will affect the transfer of power to the load presented to the transmitter.

73s

Greeting Group,

Has anyone figured out why the certain boards with the same "board number" but, "different foil side numbers" are not interchangeable? Changes in circuit(s)/etc are one thing...but...I have an 820S with a bad AF-AVR board. I can not find another board with the correct "foil side number" which ends in -03. Bob Mansker does not have any...I have several KNOWN good boards...but none have the "correct" foil side number...is this rig now for parts?

They do indeed, but a decent UPS for computer backup should output a sine wave - if it does, it will say so in the literature as it is a selling point, although this type are more expensive as all the ones I have encountered incorporate a conventional laminated iron transformer.

The only problem with the UPS route is that whilst on line and drawing normal AC power, it may not add any regulation or cleaning to that unless it is a very expensive one.

I just hate it when someone over drives their signal for whatever reason and it takes out signals a kc or two either side of their signal...

From the way you describe this, a narrow filter will do nothing to help. I'm also wondering if the rig is simply responding to a very strong signal - the old 'darkening my waterfall' complaint. This, of course, doesn't mean they are running unnecessarily high power, it may be just that the path between you is good.

If the strong signal is quite a way from the wanted signal then a narrow filter will help, but I use BPSK31 extensively with my 520 and never have had a problem. If a strong signal appears, wind back the RF gain and turn up the audio - your station will still be there somewhere and the software will find it!

Afternoon Joe,

I have, in front of me now, a TS-820S AF-AVR board with foil side number J25-1381-03. It's complete, no missing parts, all pins are straight, etc. I don't know what operational condition it's in but you can have it for the cost of shipping.

Hi friends,

If I replace the driver tube in a hybride,do I have do nutralisation?

Just pull out the old one and plug in a new one will enough? (assuming that driver is bad)

Thanks
Ravi 4S6RAV

Hi Ravi,

No you do not have to neutralize the final amplifier if you replace the driver tube.

If I may ask, what made you think the driver tube needed to be replaced? When you peak the ALC meter with the DRIVE control in TUNE mode, is the ALC meter indication stable? If it is then you don't have to replace the driver tube. If the ALC meter peaks with the DRIVE control but the ALC meter starts to drop back towards zero then the driver tube is weak and would need replacing.

Has anyone modified a hybrid to have a screen grid voltage regulator?

I am interested in hearing from anyone who has installed an old fashioned zener diode string or a mosfet shunt regulator.

I would be interested in your schematic,pictures of how you mounted the components,and wiring changes required to address the SG switch functions. Also, what is your results as far as no load and full load voltage swing.

Thanks--Terry K9TW

When I put my first ARC-5 on the air I built a regulator for the oscillator (VFO) and the PA screen and plate were unregulated. it STILL chirped when sending. Somehow I got the idea to regulate the screen voltage and adding another gas regulator tube to my power supply FIXED the chirp problem !
Not a hybrid but may help you decide.

John-- I remember the OA2 and OB2 days and the Command sets. I dont have any operational problems like cw chirping.

With regulated screen voltage would expect signal to be more linear, but no way for me to measure that. I would just like to lower screen to around 175v to180v to primarily improve the tube life and improve IMD. Exceeding screen dissipation is not good for 6146s and they are being run on the edge.

With screen voltage held under 200v should not see any measurable loss in output power. Have seen some designs that run 150volts on the screens so 175v seems like good compromise. Thanks-Terry

I would buy a 2800Hz 455Hz Inrad filter.
I guess it could be the best filter for SSB (the 2100Hz could be good but sharper than already installed Kenwood 2.4 Hz).
Is the Inrad a 8 poles easy plug-in filter or a cabled and larger size filter ?
Thank you
Paul i8ixo

Topic: 31877 Message: 31882

Hello Paul,

Below are 2 links to a couple of INRADs sideband filters for the TS-830. INRAD's website does not have a graph showing the skirts for the 2.1Khz 8.830Mhz sideband filter so I included the 2.8Khz 8.830Mhz sideband filter's link. I would suspect the 2.1Khz 8.830Mhz sideband filter will have similar graphs as the 455Khz sideband filter has.

The first link is for the 455Khz 2.1Khz sideband filter.

The second link is the 2.8Khz 8.830Mhz sideband filter.

INRAD does not show a graph for the 2.1Khz 8.830Mhz sideband filter.

http://www.inrad.net/product.php?productid=23&cat=55&page=1

http://www.inrad.net/product.php?productid=212&cat=55&page=1

I installed the INRAD 1.8Khz 5.645Mhz sideband filter in my Drake R4C and it is far superior to the Drake's factory sideband filter.

I also installed the INRAD 6Khz 5.645Mhz AM filter. I don't have an original Drake factory AM filter to compare it to but I am very pleased with the results from INRAD's 6Khz AM filter.

I'm no filter expert. I just thought you might like to see the graphs for INRAD's various sideband filters.

Chris-Just completed Item 32 Speech Processor Adjustment on pages 40&41. As usual the service manual leaves out a few thing!

They should tell you to load up normally. Then switch off SG switch and LEAVE THE HEATER SWITCH ON. You wont get any ALC indication with the heater off of the Driver Tube. A minor detail. I think they rely on previous step conditions still being in force?

1. Step 1 is OK except I would prefer that they would say "max meter reading on the Compression Scale".

2. Step 2 is OK but again they tell you to obtain S-1 reading. That would be on the S-meter scale. Then they tell you to obtain meter indication of 20db and that would be on the Compression Scale. So would be better with a multi-scale meter for them to tell you the expected value and on what meter scale.

3. Step 3 is OK but I would prefer they would tell you to set mic gain approximately 1200 o'clock or No. 5 position. I set mine at 1200 and peaked L27.

4. Step 4 (top of page 41) Is ok, but might help if they would say something like "top or far right end of black bordered ALC meter scale box". Just make it very clear what meter position and what scale you are to read.

So, I think if you load up, place SG switch to off, and leave heater switch on you will be able to complete this Item. Let me know. Terry -K9TW

31884. anyone know ts-440s??

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-16 20:20:22 UTC
From: Victor Schirmer
Topic: 31884 Message: 31884

Hey guys, my name is victor, WV1V (not a vanity I got lucky!!) my ts-440s question is: I need this rig for CW for field day, I have a MFJ CW keyer with only one input 1/4 jack and 2 rca outs. I have used this thing in the past to key american rigs that had 4 pin mic jacks, just cross 1 &4 for CW on american rigs--SGC, Patcomm 16000, etc.

My question is: how do I rig this up for a TS-400s????

any help would be great!!

Victor WV1V

Hi Terry, thanks for this.

All of that makes sense, and is exactly how I read it to be (Heater on etc), but none of it explains why I (and evidently others), can not "align" the speech processor based on this step at the top of page 41:-

Set the PROC to OFF and the COM P LEVEL control to maximum. Set the AG output to 10 mV Adjust the MIC GAIN control until the meter indicates the maximum on-scale ALC reading. Set the PROC to ON.

Adjust L27 until the same meter reading is obtained (MAX ALC on-scaled).
Mic input providing the same ALC meter reading 10mV......

This is where my 830 (or me) gets stuck..
Every step up until here works fine. I get to the point where I turn the Proc ON and adjust L27 for the same reading as where the PROC is off.
On adjusting L27 with the PROC ON I get no movement on the meter at this point, and therefore cannot obtain the same ALC maximum reading.

Cheers
Chris

Topic: 31878 Message: 31886

Chris--OK you are telling me the following:
Step A:
1. You have the Processor button off and Compression level pot max clockwise. You are in USB mode.
2. You have the meter switch to ALC position.
3. You inject 1500hz @10 mv into mic input.
4. You flip Stand-by switch to Tune.
5. You adjust mic gain until meter pointer is at the far right end of the ALC black bordered box.
6. You return to Stand-by.

Is the above correct? Where is your mic gain at? You should be between 1000 and 1100.

You then turn Processor on with Comp Level max cw. What would you expect the ALC reading to do for the same mic gain setting? Would you expect the meter to peg hard upscale far right? If you had a mic connected and whistled what would you expect ALC meter to do? Just some food for thought.

Step B:
With Processor on and Comp level set max clockwise and the mic gain not touched from above you are telling me that you have no ALC indication when you flip to Tune position? You then try to tweak L27 in attempt to obtain any ALC meter indication and get no ALC indication. Is This correct?

If so, try slowly turning mic gain up a little. It will be very sensitive and you should reach a point where it will drive meter hard up scale. Quickly turn mic gain back down until meter is at far right end of ALC black box. Mic gain pot will be sensitive. Once you have ALC indication staying at far end of ALC box you can peak L27. You may have to go back and forth several times until you no longer have to tweak the mic gain up a hair from Step A. This adjustment is a little difficult due to the ALC time constant. The meter tends to peg hard right and then slowly come back down. So it will tend to float around the max end of the ALC box until things settle down. If you switch meter to Comp you should see about 20db on Comp Scale.

Terry

Topic: 31874 Message: 31888

I can't see that regulating the screen grid supply for the PA stage is going to do any good.

The screen grid is only there to screen the cathode from the wide voltage fluctuations on the anode, and it doesn't matter in this particular application whether the screen supply is regulated or not as long as it is well decoupled both from RF and supply ripple.

Poor regulation will simply alter the bias point a little, not a problem in a PA stage.

Chris -- I forgot to mention it may be easier initially (meter switch in the ALC position) to do your adjustment with the ALC indicated level at 20db on the Compression scale as opposed to down at the high end of the ALC box. Less decay time to mess with. Terry

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Hi Terry, thanks for this.

All of that makes sense, and is exactly how I read it to be (Heater on etc), but none of it explains why I (and evidently others), can not "align" the speech processor based on this step at the top of page 41:-

Set the PROC to OFF and the COM P LEVEL control to maximum. Set the AG output to 10 mV
Adjust the MIC GAIN control until the meter indicates the maximum on-scale ALC reading. Set the PROC to ON.

Adjust L27 until the same meter reading is obtained (MAX ALC on-scaled). Mic input providing the same ALC meter reading 10mV......

This is where my 830 (or me) gets stuck..
Every step up until here works fine. I get to the point where I turn the Proc ON and
adjust L27 for the same reading as where the PROC is off.
On adjusting L27 with the PROC ON I get no movement on the meter at this point, and therefore cannot obtain the same ALC maximum reading.

Cheers
Chris

Thanks Terry....

Will hopefully get around to confirming all of this later tonight NZ time.

Cheers
Chris

Topic: 31874 Message: 31892

Andy--I agree that poor regulation will cause the bias point to vary over the RF envelope in SSB. I also agree about importance of low ripple supply and decoupling caps.

I havent looked at tube curves to see what affect the screen grid swing would be on the bias point. I know screen voltage swings approx 40 volts from no load to key down (264 to 222), but have never measured it during SSB operation. Obviously wont be that much.

As a Ham I dont want to say I dont care about linearity or IMD, but my primary concern is tube life. I believe max screen voltage for 6146Bs is 250 volts and current is 8ma per tube. So it would be very easy to exceed screen grid current and dissipation. Cant be good for tube life.

I am especially sensitive because I recently experienced 2 sets of 6146 final tube arc-overs that pegged my meter and blew open my cathode resistors. Dont want that experience any time soon.

I suspect I wont find anyone who has made this mod on the hybrids. I looked at FT-101 and FT-102s and their screen grid supply is nearly identical to Kenwoods. I guess zeners existed back then, but not sure about mosfets?

I did have a Drake T4 xmtr here a month or so ago and someone had replaced the sweep tubes with 6146s and they had installed a shunt regulator and the screen voltage was approx 150 volts. The anode was around 675 volts. Both voltages significantly lower than our hybrids. No idea how this affected the tube life in this rig. This is actually what got me thinking about possible mod to our rigs. Terry-K9TW

Subject: [TS-520_820_530_830] Re: Hybrid Screen Grid Regulation

I can't see that regulating the screen grid supply for the PA stage is going to do any good.

The screen grid is only there to screen the cathode from the wide voltage fluctuations on the anode, and it doesn't matter in this particular application whether the screen supply is regulated or not as long as it is well decoupled both from RF and supply ripple.

Poor regulation will simply alter the bias point a little, not a problem in a PA stage.

Subject: [TS-520_820_530_830] anyone know ts-440s??

Hey guys, my name is victor, WV1V (not a vanity I got lucky!!) my
ts-440s question is: I need this rig for CW for field day, I have a
MFJ CW keyer with only one input 1/4 jack and 2 rca outs. I have used
this thing in the past to key american rigs that had 4 pin mic jacks,
just cross 1 &4 for CW on american rigs--SGC, Patcomm 16000, etc.

My question is: how do I rig this up for a TS-400s????

any help would be great!!

Victor WV1V

Walt--No-you would then be keying the finals. No RF output required for this adjustment. That is done under Step 31 where you adjust ALC. Terry

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Hi Terry, thanks for this.

All of that makes sense, and is exactly how I read it to be (Heater on etc), but none of it explains why I (and evidently others), can not "align" the speech processor based on this step at the top of page 41:-

Set the PROC to OFF and the COM P LEVEL control to maximum. Set the AG output to 10 mV
Adjust the MIC GAIN control until the meter indicates the maximum on-scale ALC reading. Set the PROC to ON.

Adjust L27 until the same meter reading is obtained (MAX ALC on-scaled). Mic input providing the same ALC meter reading 10mV.....

This is where my 830 (or me) gets stuck..
Every step up until here works fine. I get to the point where I turn the
Proc ON and
adjust L27 for the same reading as where the PROC is off.
On adjusting L27 with the PROC ON I get no movement on the meter at this
point, and therefore cannot obtain the same ALC maximum reading.

Cheers
Chris

Chris--Just repeated adjustments and was able to get pretty good equal indications at far right of ALC black box or S-9 on the S-meter scale with the mic gain at just a hair beyond No. 4 position. Once I got L27 adjusted I no longer needed to tweak the mic gain to get an indication. I cant go any lower on mic gain with 10mv input. Good Luck-Terry

Thanks Terry,

So... just so I'm clear... you are adjusting Mic Gain with Proc OFF then ON to same point? that's what it states from memory... point of exercise is to have ALC reading same position with Proc ON and OFF.

Cheers
Chris

On 17/06/2011, at 11:27 AM, Terry Wagoner wrote:

> Chris--Just repeated adjustments and was able to get pretty good equal indications at far right of ALC black box or S-9 on the S-meter scale with the mic gain at just a hair beyond No. 4 position. Once I got L27 adjusted I no longer needed to tweak the mic gain to get an indication. I cant go any lower on mic gain with 10mv input. Good Luck-Terry

Yes--Objective is for a given mic gain setting with 10mv applied to have same ALC reading (max) with Processor on and off. You should not have to adjust mic gain or input signal level once balanced. You should be able to flip to Tune with Proc on and off and see approx the same max ALC indication.

If you initially get no indication (I think that is your problem?) you can move mic gain up slightly until you get an indication. It wont take much and will be very touchy and will want to peg the meter. Only other choice you have is to set audio generator output higher as others suggested. I chose to just increase mic gain until I got an indication. After I found that point I no longer needed to touch the mic gain. If I had to increase mic gain each time then it would not be a valid adjustment. As I mentioned I ended up getting pretty good matched ALC indication with mic gain just a hair past No.4. Terry

Hi Mike,

Thanks for the advice.
In my 520, I am not getting full power out in all bands.80-100W in 80 &
40 meters and around 50-65W in others.Then I can remember some one suggested to
clean the MODE and BAND switches.Which I did with a contact cleaner liquid but
more or less with same results.
I was wondering whether my driver is bad or transmitter section needs
alignment.However, when tuning, ALC meter is stable. So now it appears
re-alignment is necessary.If I follow the instructions in the manual for TX alignment, I
will be OK I guess.

Hi Ravi,

No you do not have to neutralize the final amplifier if you replace the driver tube.

If I may ask, what made you think the driver tube needed to be replaced? When you peak the ALC meter with the DRIVE control in TUNE mode, is the ALC meter indication stable? If it is then you don't have to replace the driver tube. If the ALC meter peaks with the DRIVE control but the ALC meter starts to drop back towards zero then the driver tube is weak and would need replacing.

Well the Radio blew the fuse as designed. Replace the caps and check the high voltage to be sure it is correct. If all seems well, forget it and chalk it up to age. I would purchase a spare set to be on the safe side. It's an old radio and I know how much fun they are to use, so have fun and don't try and second guess age. Have fun.Brad KB2CHY

Subject: [TS-520_820_530_830] Capacitors blown off!!

Hi Friends

Today my TS520SE stopped suddenly with a 'pop'.

When checked, the AC fuse was blown.I opened the covers and noted that one of the small ceramic capacitors across high voltage caps was blown. This is noted as C17 or C18 in the circuit diagram. The high voltage caps are C19 & C20 connected to 800V line in the rectifier unit.

I can replace both after discharging high voltage caps.My worry is why this has happened? Is it due to aging of the caps or for some other reason.Looks like caps are originals but not sure as previous repair notes are not available.
Appreciate any views/suggestions.73's de 4S6RAV (Ravi)

The ham said he thought it was an early model. It's serial number is 390585, and the fan cover on the back is a gold screen. Not the black cover on most models. Also the vfo frequency reading area is completely white.

Some one installed a switch on the bottom. I appears this may cut a cw filter on and off, is this a mod that was done?

Also the receive strength sometimes comes and goes and can be corrected by putting pressure on the band switch. Do you think a cleaning will fix this?

Thanks Guys, KB4MNG Brian in nc

Brian,

I do think that the "early" models have the screened fan as you say. These rig have been around for awhile...a good cleaning of ALL controls can't hurt...DEOXIT and some "canned air" work well. I would look VERY close as to what that switch is wire to. Very often these rigs get the CB HACK JOB aka "FREE BANDING" Double check any crystal frequency with one on the schematic.

So you plug your key into the key jack, make a cable from the direct connector to your TS440 and then choose iambic....

You do not send CW with the mic jack !.
 there is A 1/4 inch KEY jack on the rear panel of the TS440s.
On the keyer, Use the Standard RCA jack that is positive keying (not grid block)
with a cable with male RCA to male 1/4 inch single circuit plug to the radio.

Your 1/4 inch socket on the Keyer is a 2 circuit (stereo) phone input for the
paddle.
Hope to hear you on the CW frequencies soon.

Subject: [TS-520_820_530_830] anyone know ts-440s??

Hey guys, my name is victor, WV1V (not a vanity I got lucky!!) my
ts-440s question is: I need this rig for CW for field day, I have a
MFJ CW keyer with only one input 1/4 jack and 2 rca outs. I have used
this thing in the past to key american rigs that had 4 pin mic jacks,
just cross 1 &4 for CW on american rigs--SGC, Patcomm 16000, etc.

My question is: how do I rig this up for a TS-400s????

any help would be great!!

Hi Terry, in a nutshell,

It doesn't weigh up here.

Following to the letter the service manual and then taking into account your notes, the final situation is that I end up with full on-scale deflection of ALC (ie end of black ALC setting), with processor on and full scale (pegged meter) deflection without PROC engaged, just Mic.

God knows but I cannot get ALC to be the same with PROC ON and PROC OFF.

Thanks
Chris

Terry I meant to say "full on-scale deflection of ALC (ie end of black ALC setting), with processor on and full scale (pegged meter) deflection without PROC NOT engaged, just Mic.

I agree, a good cleaning would be a good idea. I also recommend inspecting the band switch wafer assemblies for a lose ground(s) and/or connections.

The all white dial indicates the 520 you have is the first model in the 520 series (80 thru 10, no WARC Bands).

The TS-520 (white dial model) has an input power rating of 200 watt PEP on sideband (USB and LSB) and a DC input power rating of 160 watts in CW mode. This relates to a an average power output of 110 watts on sideband and 90 watts output on CW.

If you do not have the TS-520 operator and service manuals, go to Gordon's website, www.n6wk.com/kenwood/ and download them. Take the time to read the operator's manual before you attempt to operate the TS-520. Reading the operators manual will allow you to become familiar with the various controls on the front and rear panel. Pay close attention to the rear panels "SG" switch. The rear panel SG switch must ALWAYS be in the "ON" position for normal operation. The other controls on the rear panel are the bias pot and the RF indicator pot. The function of these control is discussed in the manual. In addition, there is a 9 pin socket on the rear panel. This socket is where the remote VFO (optional feature) connects to the 520. If you do not have the remote VFO (VFO-520 or VFO-820) then the factory jumper plug must be plugged into this socket. If you do not have the factory jumper plug (Gordon has this plug, contract Gordon for details on purchasing the plug) then you can use a simple wire jumper between pins 8 and 9. See the operators manual for details which pins are 8 and 9. Without pins 8 and 9 connected (factory jumper plug or piece of wire), the 520 will power up but not work.

If do you have a 50 ohm dummy load then I highly recommend you borrow or purchase one. The dummy load should have a power rating of at least 300 watts, higher if you are using a linear amplifier with the 520.

Again, take the time to read the operators manual before you operate the 520.

Chris--This appears different than what you originally reported of getting no ALC indication? Why now getting ALC indication? What did you do different? Where is your mic gain set at? I would not leave meter pegged to long as it is hard on the movement. I would slowly turn down mic gain until I could get meter off the peg.

With Proc off key rig and back off mic gain to get ALC at 20db or at least off the peg and on the meter scale. Now turn on Proc and key rig and report back what your ALC reading is. Based on what you are reporting I would expect it to be something less than far right of ALC black box? Assuming it is somewhere in the ALC box window can you adjust L27 and bring the reading up? Terry

Terry I meant to say "full on-scale deflection of ALC (ie end of black ALC setting), with processor on and full scale (pegged meter) deflection without PROC NOT engaged, just Mic.

[Non-text portions of this message have been removed]

[Non-text portions of this message have been removed]

31912. Re: [TS-520_820_530_830] Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-17 14:08:00 UTC
From: Chris Parnell
Topic: 31878 Message: 31912

Hi Terry,

The only difference from my original post is that I increased the "gain" on the input (Mic gain), therefore got an ALC reading.
Point is that I cannot align the ALC for PROC ON & PROC OFF... not sure why...

I don't leave it pegged, I immediately back down the Mic gain to compensate.

> Based on what you are reporting I would expect it to
> be something less than far right of ALC black box? Assuming it is somewhere in
> the ALC box window can you adjust L27 and bring the reading up?
>

Once I have done the initial adjustment Terry, and get the ALC to the far right of the "ALC BOX" I cannot get L27 to peak the reading up to the same.

Hope this makes sense..

Cheers
Chris

[Non-text portions of this message have been removed]

31913. Re: [TS-520_820_530_830] Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-17 15:13:09 UTC
From: Terry Wagoner
Topic: 31878 Message: 31913

Chris--I will give some more thought. Not sure what is going on. I am just about out of ideas.

I just repeated the test on my daily operating TS-830 with the covers on the rig. I just unplugged the mic and brought the test equipment to the operating position.

I use a spare mic connector and clipped the generator output to it with mini-clips to pins 1 and 2 (bottom 2 pins). I have the mic gain set exactly at No. 4 position. I set SG switch on rear of rig to off and turn on rig and heater switches. Let it warm up a little.

I used accurate HP True RMS audio voltmeter to set 1500 hz sine wave from Wave Tek generator to exactly 10 mv.

I turned Proc off and set Comp level to max CW. I set mode switch to USB. I place meter switch in ALC position.

I then flip to Send and get ALC meter indication that is just outside the max end of the black ALC box. Maybe a needles worth.

I flip back to Stand-by and turn on Proc button. Meter is still in ALC position and I have not touched mic gain pot.

I flip to Send and the ALC meter indication is a little bit more outside the black ALC box. It could be adjusted a little to get a match if I had the covers off, but close enough. I switch the meter from ALC to Comp and it indicates just a little above 20db on the Comp scale.

I repeatedly switched Proc on and off and get the same results. In short my as found condition for my daily operator is very close to being right on the same indicated level on the ALC meter scale (near max on black border) with Proc on and off.

At this point Chris not sure I can be of any more help? I will think about it some more and if I come up with something will write.

Whatever you do you should not have to increase mic gain position or increase audio generator output level above 10 mv. Depending on the pre-amp gain in your rig you may have to be a little higher than position 4 on the mic gain , but I wouldnt think much higher.

Also, you might want to measure the sig gen level at your mic connection when flipped to Send to make sure it is staying at 10 mv. Mine does not vary from Stand-by to Send. Other than that I think I have exhausted my experience. Good luck Terry

Hi Terry,

The only difference from my original post is that I increased the "gain" on the input (Mic gain), therefore got an ALC reading.
Point is that I cannot align the ALC for PROC ON & PROC OFF... not sure why...

I don't leave it pegged, I immediately back down the Mic gain to compensate.

> Based on what you are reporting I would expect it to
> be something less than far right of ALC black box? Assuming it is somewhere in

> the ALC box window can you adjust L27 and bring the reading up?
>

Once I have done the initial adjustment Terry, and get the ALC to the far right of the "ALC BOX" I cannot get L27 to peak the reading up to the same.

Hope this makes sense..

Cheers
Chris

31914. Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-17 15:43:32 UTC
From: w5rkl
Topic: 31878 Message: 31914

Chris,

Are you adjusting L26 for maximum "ALC" meter scale indication or a maximum "meter" indication?

The first 3 steps in the speech processor adjustment calls for "maximum meter" indication. The only step that clearly states to adjust L27 for maximum ALC "meter scale" indication is the last step, processor ON and OFF.

The only portion of the adjustment where it clearly states to adjust for maximum ALC scale indication is the last step, processor ON and OFF.

Also, how you are determining the 1.5Khz audio signal level? A scope or an audio meter, VTVM?

Also, have you tried taking voltage readings? There could be a failed component in the IF processor circuit that is causing your problem. Use the 830 high resolution schematic (has voltages listed in RED) when taking voltage readings.

73s
Mike

Terry - using a lower screen grid voltage is the way to go for extended tube life, I'd have thought. The maximum power output would be reduced, which would be the main mechanism by which dissipation throughout the tube would be kept down.

Yes, zeners were available then as were gas regulators, but it seems none of the manufacturers deemed this a worthwhile move.

Looking through many schematics from the 60s and 70s both amateur and professional I haven't seen any designs that use screen grid regulation, so am of the opinion that if the designers didn't see the benefit, chances are neither will we.

I do wonder if regulating the plate supply would be an advantage though, although we would be dealing with a fair bit of dissipation in the pass device.

Why regulate the plate supply? Pentodes don't need it.

And with SSB the duty cycle on the plate supply is low.

Topic: 31878 Message: 31917

Hi Mike-- I am just about out of ideas.

You are right they are looking for max ALC indication (far right end of black bordered box) and not max meter movement indication.

I was able to get good meter indications and adjust for a good match on my back up rig on the test bench just fine once I had read the steps several times and figured out what meter indications they were looking for.

I thought I would check the as-found on my operating rig this morning to validate test procedure on another 830. I found it to be close enough (within needles worth just outside far end of ALC box) until next time I do a complete alignment. I verified that the 1500 hz 10 mv signal was not moving around during the test. I have to have mic gain at No, 4 position for 10mv signal to work.

Originally as I understand it Chris could not get any ALC indication with 10mv injected at mic input. I am not sure what he did to get it other than increase the mic gain setting slightly? I think Chris is now getting meter to peg high. If this is true I would turn mic gain down slightly to get it off peg. Just a slight adjustment of mic gain will result in big change in meter indication.

With meter pegged L27 will have no effect.

I wishing that we could use Skype or some other means to demonstrate some of this stuff in real time. Could do it with Skype one on one, but others couldnt view or share in the discussion. If you and/or Gordon had a lot of time you could make You Tube videos of the entire alignment procedure and show different ways to accomplish using different test equipment. Would be fun but a lot of work.

I am looking for a 40 mhz sweep gen so I can check the PLL filters. Cant really justify buying one for just this test and for use on just my rigs alone.

Sweep gen and spectrum analyzer are about only two pieces of test gear I dont have that would make aligning these hybrids a breeze.

Thanks--Terry - K9TW

Subject: [TS-520_820_530_830] Re: Speech Processor alignment

Chris,

Are you adjusting L26 for maximum "ALC" meter scale indication or a maximum "meter" indication?

The first 3 steps in the speech processor adjustment calls for "maximum meter" indication. The only step that clearly states to adjust L27 for maximum ALC "meter scale" indication is the last step, processor ON and OFF.

The only portion of the adjustment where it clearly states to adjust for maximum ALC scale indication is the last step, processor ON and OFF.

Also, how you are determining the 1.5Khz audio signal level? A scope or an audio meter, VTVM?

Also, have you tried taking voltage readings? There could be a failed component in the IF processor circuit that is causing your problem. Use the 830 high resolution schematic (has voltages listed in RED) when taking voltage readings.

Andy--I dont think we would lose very much output power with regulated screen. Probably not discernable and certainly not on the receiving end. Yes plate supply would be tough to do. Gets involved with main xfmr esr and host of other things over my head and pass device would help keep shack warm!

Yes-- most if not all the rigs of this design and vintage did not include any form of screen grid regulation. It would have increased the price of the rigs.

I know in the old days it was pretty much expected to have a good stiff bias supply and a regulated screen supply. The old VR tubes were the way to go back in the 60s. I still have some old ARRL handbooks from the tube days and they have plenty of circuits that employed regulated screen supplies. It was just expected to ensure linearity. I have two tone generator here but never been very successful at getting any meaningful test from it. I keep waiting for a spectrum analyzer to fall in my lap!

I will just let it go for now and put on back burner.

Thanks for responding and sharing. Terry

Subject: [TS-520_820_530_830] Re: Hybrid Screen Grid Regulation

Terry - using a lower screen grid voltage is the way to go for extended tube life, I'd have thought. The maximum power output would be reduced, which would be the main mechanism by which dissipation throughout the tube would be kept down.

Yes, zeners were available then as were gas regulators, but it seems none of the manufacturers deemed this a worthwhile move.

Looking through many schematics from the 60s and 70s both amateur and professional I haven't seen any designs that use screen grid regulation, so am of the opinion that if the designers didn't see the benefit, chances are neither will we.

I do wonder if regulating the plate supply would be an advantage though, although we would be dealing with a fair bit of dissipation in the pass device.

Hi terry,

Before performing any alignment steps, one should read the alignment steps thoroughly to ensure one understands what the alignment step is suppose to do and what indication one should see. That also is where reading the service manual comes into play. Knowing what each stage does helps one to understand what an alignment step is actually saying.

Most alignment adjustments, excluding oscillator frequency adjustments, are based on setting a level or adjusting for either a maximum or minimum indication on a meter.

The alignment steps listed in the service manuals are how the factory, with all the sophisticated test gear, says it should be and under "ideal" situations. That doesn't always mean one will get the exact same indications. Aging components can affect how an alignment step will produce the desired result. Failed components, leakage diodes, resistors that have increased in resistance which can affect how a transistor or other device works, will affect how the alignment step end result is.

If the meter pegs full scale, I would recommend reducing the signal level at the signal "source" instead of reducing the MIC gain setting. If there is no way to determine the true signal level then one can only "guess" the signal level is correct. That's why I always recommend setting the controls as called for in the alignment steps then start with the RF and/or AF signal level at zero. At that point, the signal source level can be increased until an indication is seen. AT that point, stop increasing the signal level and start the alignment adjustments. You can always increase the signal level if necessary.

If the alignment step can't be performed correctly,even after trying several times, such as in this case, then one should stop performing the alignment step and start troubleshooting the circuit. Take voltage readings and compare them with the factory voltage levels (the TS-830 high resolution schematic has the voltage levels in RED). An incorrect voltage level, for example, at a transistor's Gate, Source, Drain, Emitter, Base, or Collector that is significantly different than what the factory says the voltage should be is a clear indication a problem exits. This problem can be caused by a failed diode, a resistor that has significantly increased in resistance, or a bad/broken foil run/solder connection. Simply redoing the alignment step, even after doing it a number of times, will not result in a different indication.

There is no real reason to regulate the final amplifier supply. The screen voltage varies too often and regulating the supply would be a waste of time and would not produce any added benefit. The supply for the 830's final amplifier is quite stable for what it's designed to do.

Regulated supplies are more important with oscillators such as VFO/LMO/PTO, carrier generators, and the like.

The steps in question say to adjust the mic gain for " max meter indication with 50mv and 10mv injected. It does not say to vary the input signal.

When you adjust the mic gain with the specified audio frequency and signal level applied you can complete these steps as written. Until I was certain that Chris was performing the steps as written, I didnt want to direct him to start trouble shooting.

At this point I will ask him to work with you on trouble shooting as you have better understanding of how the circuits work.

These service manuals are pretty well translated, but could be better. I wrote procedures for nuclear power and I am pretty picky about how to write test procedures. On these steps an approximate mic gain setting could have been listed to get you in the ball park. They also could do a much better job through out the manual describing the expected outcome, meter indications etc. Would be very easy to say what position meter switch is to be in and what scale to read on. Just my opinion.

I especially like the circuit description on the top of Page 7 under the Carrier Oscillator heading that talks about two QUARTS crystals! That is a lot of xtals!

Chris--If you feel you are literally following the procedure steps as written and cant get the expected outcome then it is time to move on to troubleshooting.

Please work with Mike on troubleshooting your problem. He is much more experienced and understands how these circuits work and can help you shoot trouble down to discrete component level if necessary.

I would like to know what you end up determining the problem is. Best 73s-Terry K9TW

>
>

Agreed.
Some better hi-fi amps have stabilised supplies for the output stages, presumably this aids linearity, but I would expect it to reduce output device dissipation during quiescent periods when the supply would normally be at a maximum. Presumably the PA in a transmitter would benefit in the same way.

I doubt very much that the small benefit of reduced dissipation would anywhere near compensate for the added expense and complication though - the idea was thrown in for discussion rather than as a practical suggestion.

Andy- I just found a real interesting article where a fellow modified his TS-820s with a screen grid shunt regulator circuit. He gives technical basis for why and details on how he selected the components and wiring installation directions taking into account the SG switch.

He also talks about installing a screen grid bleeder which is pretty common in the larger tetrode tube amps. I dont know if you could ever get the SG switch in an in between position or not? Could certainly damage tube quickly. A bleeder would protect against this.

I havent studied this article closely yet, but it appears to be exactly what I was looking for. The article did not identify the author. I am going to see if I can find out who and contact the person. You can find it if you Google "TS-820 mosfet shunt regulator". It comes up under "desert hound" ??? It is cached. Let me know what you think. Thanks Terry K9TW

Hi Terry / Mike.....

I am using a Marconi Instruments 2955 Radio Communications Test Set. - Good piece of kit. Here's what I see when I follow your instructions:

> I use a spare mic connector and clipped the generator output to it with
> mini-clips to pins 1 and 2 (bottom 2 pins).
>
Exactly the same as me Terry, except my mini clips are connected directly to the Mic Socket on the Rig not a 4 pin Mic connector, but no differemce.

> I have the mic gain set exactly at
> No. 4 position.
>
Same here

> I set SG switch on rear of rig to off and turn on rig and heater
> switches. Let it warm up a little.
>
Same here

> I used accurate HP True RMS audio voltmeter to set 1500 hz sine wave from Wave
> Tek generator to exactly 10 mv
>
Using the above I set it to AF Generator - 1.5Khz 10mV output.

> turned Proc off and set Comp level to max CW. I set mode switch to USB. I
> place meter switch in ALC position.
>

Same here

>
> I then flip to Send and get ALC meter indication that is just outside the max
> end of the black ALC box. Maybe a needles worth.
>
At this point in my TS-830s, with Mic set to 4, AF Gen set to 1500Hz and 10mV and USB mode, I flick to send and I get full scale meter deflection in ALC mode (Full meter deflection, not on-scale ALC meter deflection, so if you look at s-meter scale, it's S9+40dB +).

>
> I flip back to Stand-by and turn on Proc button. Meter is still in ALC position
> and I have not touched mic gain pot.
>
With Proc on, and Proc level fully clockwise, not adjusting any gains at either the AF Gen or Mic gain, I get a meter reading in ALC mode of around S9+20dB now.. (I am only using the S-Meter scale as it's easier for you to gauge what I'm saying and seeing.

At this point, I turn PROC OFF, and adjust VR-7 down so that I get maximum "On-Scale" ALC reading, so now I get an accurate end of scale reading without PROC ON, which on the S-Meter is S-9.
I check where VR-7 is now within it's VR scale and notice it's almost at minimum.

>
> I flip to Send and the ALC meter indication is a little bit more outside the
> black ALC box.
>
So now that I have adjusted VR-7 for full on-scale ALC meter reading, with PROC OFF, I put PROC ON and the reading drops to around the end of the letter C of the word ALC on the meter, which is about S-6 on the S-Meter.

> It could be adjusted a little to get a match if I had the covers
> off, but close enough.
>

I check L27 and find it's at it's peak, so I cannot go any higher and align them with the PROC ON.

> I switch the meter from ALC to Comp and it indicates just
> a little above 20db on the Comp scale.
>
Mine (at this point) indicates around +40dB of Comp on the Comp meter, so I adjust L26 for 20dB reading.

I will need to do some component checking in the circuit around the Processor as Mike and yourself have recommended.

I have a HP scope, RF Millivoltmeter and the Marconi Test set I mentioned.

Thanks
Chris, ZL1CDP

[Non-text portions of this message have been removed]

31926. Fwd: [TS-520_820_530_830] Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-17 23:13:20 UTC
From: Chris Parnell
Topic: 31926 Message: 31926

Sorry gents,

Last statement should have read, I adjust VR-5 for 20dB (not L26).

Cheers
Chris

>
>> I use a spare mic connector and clipped the generator output to it with
>> mini-clips to pins 1 and 2 (bottom 2 pins).
>>
> Exactly the same as me Terry, except my mini clips are connected directly to the Mic
Socket on the Rig not a 4 pin Mic connector, but no differemce.
>
>
>> I have the mic gain set exactly at
>> No. 4 position.
>>
> Same here
>
>
>> I set SG switch on rear of rig to off and turn on rig and heater
>> switches. Let it warm up a little.
>>
> Same here
>
>
>> I used accurate HP True RMS audio voltmeter to set 1500 hz sine wave from Wave
>> Tek generator to exactly 10 mv
>>
> Using the above I set it to AF Generator - 1.5Khz 10mV output.
>
>> turned Proc off and set Comp level to max CW. I set mode switch to USB. I
>> place meter switch in ALC position.

>>
>
> Same here
>
>
>>
>> I then flip to Send and get ALC meter indication that is just outside the max
>> end of the black ALC box. Maybe a needles worth.
>>
> At this point in my TS-830s, with Mic set to 4, AF Gen set to 1500Hz and 10mV and USB mode, I flick to send and I get full scale meter deflection in ALC mode (Full meter deflection, not on-scale ALC meter deflection, so if you look at s-meter scale, it's S9+40dB +).
>
>>
>> I flip back to Stand-by and turn on Proc button. Meter is still in ALC position
>> and I have not touched mic gain pot.
>>
> With Proc on, and Proc level fully clockwise, not adjusting any gains at either the AF Gen or Mic gain, I get a meter reading in ALC mode of around S9+20dB now.. (I am only using the S-Meter scale as it's easier for you to gauge what I'm saying and seeing.
>
> At this point, I turn PROC OFF, and adjust VR-7 down so that I get maximum "On-Scale" ALC reading, so now I get an accurate end of scale reading without PROC ON, which on the S-Meter is S-9.
> I check where VR-7 is now within it's VR scale and notice it's almost at minimum.
>
>>
>> I flip to Send and the ALC meter indication is a little bit more outside the
>> black ALC box.
>>
> So now that I have adjusted VR-7 for full on-scale ALC meter reading, with PROC OFF, I put PROC ON and the reading drops to around the end of the letter C of the word ALC on the meter, which is about S-6 on the S-Meter.
>
>
>> It could be adjusted a little to get a match if I had the covers
>> off, but close enough.

Topic: 31878 Message: 31927

Chris-- I trust with that test equip you have accurate 10mv and 50 mv 1500hz test signals.

With your mic gain at No. 4 it appears you have much more gain than I do in my mic pre-amp circuit. There is nothing magic about mic setting of 4 it is just where I can get a good match at far right end of ALC black box.

With Proc off and 10mv injected it doesnt take much adjustment right around the No. 4 setting of the mic gain to peg the meter or to have it fall back and have no meter indication. I do know with both of my rigs I end up at very close to No.4 on the mic gain to get a meter indication at the end of ALC box.

I assume you have tried adjusting the mic gain down while leaving required 10mv signal injected? I found it a little touchy. When you first reported no meter indication that is why I suggested turning mic gain up a little. Maybe I am starting to get confused regards what your problem is.

If turning mic gain down a little doesnt help then I would say it is on to troubleshooting with Mike.

Terry

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Hi Terry / Mike.....

I am using a Marconi Instruments 2955 Radio Communications Test Set. - Good piece of kit.
Here's what I see when I follow your instructions:

> I use a spare mic connector and clipped the generator output to it with
> mini-clips to pins 1 and 2 (bottom 2 pins).
>
Exactly the same as me Terry, except my mini clips are connected directly to the Mic Socket on the Rig not a 4 pin Mic connector, but no differemce.

> I have the mic gain set exactly at
> No. 4 position.
>
Same here

> I set SG switch on rear of rig to off and turn on rig and heater
> switches. Let it warm up a little.
>

Same here

> I used accurate HP True RMS audio voltmeter to set 1500 hz sine wave from Wave

> Tek generator to exactly 10 mv
>
Using the above I set it to AF Generator - 1.5Khz 10mV output.

> turned Proc off and set Comp level to max CW. I set mode switch to USB. I
> place meter switch in ALC position.
>

Same here

>
> I then flip to Send and get ALC meter indication that is just outside the max
> end of the black ALC box. Maybe a needles worth.
>
At this point in my TS-830s, with Mic set to 4, AF Gen set to 1500Hz and 10mV
and USB mode, I flick to send and I get full scale meter deflection in ALC mode
(Full meter deflection, not on-scale ALC meter deflection, so if you look at
s-meter scale, it's S9+40dB +).

>
> I flip back to Stand-by and turn on Proc button. Meter is still in ALC position
>
> and I have not touched mic gain pot.
>
With Proc on, and Proc level fully clockwise, not adjusting any gains at either
the AF Gen or Mic gain, I get a meter reading in ALC mode of around S9+20dB
now.. (I am only using the S-Meter scale as it's easier for you to gauge what
I'm saying and seeing.

At this point, I turn PROC OFF, and adjust VR-7 down so that I get maximum
"On-Scale" ALC reading, so now I get an accurate end of scale reading without
PROC ON, which on the S-Meter is S-9.
I check where VR-7 is now within it's VR scale and notice it's almost at
minimum.

>
> I flip to Send and the ALC meter indication is a little bit more outside the
> black ALC box.
>
So now that I have adjusted VR-7 for full on-scale ALC meter reading, with PROC
OFF, I put PROC ON and the reading drops to around the end of the letter C of
the word ALC on the meter, which is about S-6 on the S-Meter.

> It could be adjusted a little to get a match if I had the covers
> off, but close enough.
>

I check L27 and find it's at it's peak, so I cannot go any higher and align them
with the PROC ON.

> I switch the meter from ALC to Comp and it indicates just
> a little above 20db on the Comp scale.
>
Mine (at this point) indicates around +40dB of Comp on the Comp meter, so I
adjust L26 for 20dB reading.

I will need to do some component checking in the circuit around the Processor as
Mike and yourself have recommended.

I have a HP scope, RF Millivoltmeter and the Marconi Test set I mentioned.

Thanks
Chris, ZL1CDP

I have a whistler 500 watt/800 watt peak inverter.I am asking if anyone in the group knows if this unit has the right kind of output for a Ts-520s ,like wave form.The generator we were going to use for feild day
did not have stable enough output.Going to use two 55 amp and a 33 amp
battery with the inverter.

31929. Re: [TS-520_820_530_830] Re: Speech Processor alignment

Hi Terry, you got me thinking about the signal coming out of the AF Gen (as I have no attenuation in there)...

So I got some test reference dBmA numbers against my calibrated probe and wrote down the numbers for 5mV, 10mV and 50mV before I started again.
So... re-did the whole thing and of course, its more in line with your "Mic Gain 4" setting now, but still a huge difference when going from PROC OFF to PROC ON with regards to ALC readings.

When the ALC meter is at full ALC gauge reading with PROC ON, the second I turn the PROC OFF, the ALC shoots right over to the right hand side of the meter.

I may record a small video and send it to you... easier to see what I mean and what i'm doing.

Turning the Mic gain up and down of course makes a difference, but the point is, I still cannot get PROC OFF and PROC ON to align with the ALC readings.

Cheers
Chris

Chris--

Do you have Skype? Maybe we could connect on Skype and perform each step together on our rigs and see at what step we differ. Not sure if we could have clear enough real time video or not for this to work. Not sure about our time difference, but could schedule it Zulu/GMT just as we would a QSO.

Maybe Mike or Gordon would be better to do this with you as they repair these rigs for a living? As you know I had never performed this step until you asked about it. In fact I have never completed a full alignment as I dont have sweep generator. I have just done selected steps.

Terry

Subject: Re: [TS-520_820_530_830] Re: Speech Processor alignment

Hi Terry, you got me thinking about the signal coming out of the AF Gen (as I have no attenuation in there)...

So I got some test reference dBmA numbers against my calibrated probe and wrote down the numbers for 5mV, 10mV and 50mV before I started again.
So... re-did the whole thing and of course, its more in line with your "Mic Gain 4" setting now, but still a huge difference when going from PROC OFF to PROC ON with regards to ALC readings.

When the ALC meter is at full ALC gauge reading with PROC ON, the second I turn the PROC OFF, the ALC shoots right over to the right hand side of the meter.

I may record a small video and send it to you... easier to see what I mean and what i'm doing.

Turning the Mic gain up and down of course makes a difference, but the point is, I still cannot get PROC OFF and PROC ON to align with the ALC readings.

Cheers
Chris

Topic: 31878 Message: 31931

Hi Terry,

Yes I do have Skype, and am happy to try this... I have just sent you and Mike an email off list with some voltage measurements.

Cheers
Chris

[Non-text portions of this message have been removed]

31932. Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-18 12:03:04 UTC
From: Terry Wagoner
Topic: 31878 Message: 31932

Chris--Did you record the original positions of L26,L27, and VR-5? Hope you did as it is good practice. If so suggest you return them to as found and assume no previous owner had significantly tweaked them.

I guess I was under impression that you were doing full alignment to give rig a "spring tune-up" and not to correct a operational problem in SSB mode? Or did you think source of your "low power" was an alignment issue?

I assume that before you started to align the rig that you had it on the air and that SSB worked with just the mic and with Processor on and you got good audio reports in both modes?

So, before trouble shooting your mic or pre-amp circuits. Try this:
1. Load into dummy load.
2. Plug in head phones and turn on Moni so you can listen to your audio.
3. Set mic gain to where you would normally run it and use your sideband voice and normal distance from the mic (1-2inches) and then watch ALC indications as you speak. Should just start seeing some upward flicks on the ALC meter. For my rig that is with the mic gain at 1130 to 1200. Others report they get this with mic gain at 1000. Neither of my rigs will do this. Owners manual says to set mic at 1200. Variables include what mic using, your voice and distance from the mic.
4.Leave mic gain. Switch meter to Comp scale. Turn on Processor and increase Compression level to around 4 and speak into mic. On voice peaks suggest you should see around 8% to 10% on Comp scale. I run my Compression level pot between 3 and 4. At that level I get 10% on Comp meter scale and I like the way it sounds in the headphones and more importantly I get good reports and can break those DX pile-ups running barefoot. Some fellows run much more compression, but you can hear fan and other back ground noise in the shack. I dont care for that kind of audio.

The point of all of this is to prove that your mic pre-amp, ALC circuits, and processor circuits are all working and you can modulate the rig properly and get good audio. I thought your original problem was low output but no problem generating a ssb signal.

If this is true then you can go back to your alignment procedure which is just a fine tuning and not trying to correct an operational problem.

If not true then as Mike suggests you have a supply voltage or component problem and can begin your trouble shooting with his help. Terry

31933. Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-18 16:24:07 UTC
From: Terry Wagoner
Topic: 31878 Message: 31933

Chris: I cant help you too much with power supply voltages. The only time I have had occasion to measure anything on the PS board was related to 210A and 470 screen dropping resistor.

I have measured all tube voltages. In my own rigs I have new filter caps at 120uf as opposed to factory 100uf. My anode voltage no load is approx 940vdc and approx 820vdc loaded to 225ma. This is with 120 vac line voltage which tends to run high.

Terry

31934. Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-18 20:31:42 UTC
From: Terry Wagoner
Topic: 31878 Message: 31934

Chris--No one ever accused me of being very smart, but I will never fail due to lack of effort!

1. You are telling us your problem is that with 1500 hz @ 10 mv injected into mic jack,mic gain setting around No. 4(Processor OFF), in USB mode, meter in ALC position, that when you flip to send the meter pegs off scale right hand side of the meter. Is this true?

2. The expected response would be for the meter to deflect to the far end of the ALC black box scale or somewhere close either side of the Max ALC range and not peg.

3. I dont believe this has anything to do with your Processor or Comp Level setting. Comp level pot is not in the circuit when Processor is off.

4. I am suspicious of Alignment Step 31. I remember telling you that I had difficulty doing this step as written and you had not completed it yet. I suggest you go back and repeat this step.

5. In Step 31 you adjust the ALC meter Zero (trim pot VR-6) and you adjust the Maximum ALC reading (far right end of ALC black box)by adjusting trim pot VR-7. VR-6 is easy and VR-7 is a little tricky. When you complete this step you should be able to flip to send with 10 mv signal injected and get max ALC reading and not peg the meter full scale or any ALC indication very far past the black border. If that is not how you left this step then this is likely your problem.

6. As an experiment. Record the setting of VR-7. Flip to Send with Processor off. When meter pegs hard right reduce mic gain slightly to just get if off the peg. Then slowly tweak trim pot VR-7 (on IF board at base of Q31). You should be able to move meter indication down to the ALC box max border or S9.

7. If you can move ALC reading down then go ahead and repeat Step 31 before returning to Step 32. Make sure Step 31 is as accurate as you ca.

8. If you cannot adjust ALC indication down with trim pot VR-7 then there is likely something wrong with ALC meter driver Q30 and Q31 or with Q19 and Q20 on the AF board.

Good Luck-Terry K9TW

31935. Re: [TS-520_820_530_830] Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-18 21:02:11 UTC
From: Terry Wagoner
Topic: 31878 Message: 31935

Chris--I forgot to add as a point of reference my pots and coils are as follows:
VR-5 = 1100
VR-7 = 0930
L26 slug is near the top at 1130
L27 slug is near the top at 1000

I am going back and repeating my Step 31. Terry

From: Terry Wagoner <wagstw46@...>

Subject: [TS-520_820_530_830] Re: Speech Processor alignment

Chris--No one ever accused me of being very smart, but I will never fail due to lack of effort!

1. You are telling us your problem is that with 1500 hz @ 10 mv injected into mic jack,mic gain setting around No. 4(Processor OFF), in USB mode, meter in ALC position, that when you flip to send the meter pegs off scale right hand side of the meter. Is this true?

2. The expected response would be for the meter to deflect to the far end of the ALC black box scale or somewhere close either side of the Max ALC range and not peg.

3. I dont believe this has anything to do with your Processor or Comp Level setting. Comp level pot is not in the circuit when Processor is off.

4. I am suspicious of Alignment Step 31. I remember telling you that I had difficulty doing this step as written and you had not completed it yet. I suggest you go back and repeat this step.

5. In Step 31 you adjust the ALC meter Zero (trim pot VR-6) and you adjust the Maximum ALC reading (far right end of ALC black box)by adjusting trim pot VR-7. VR-6 is easy and VR-7 is a little tricky. When you complete this step you should be able to flip to send with 10 mv signal injected and get max ALC reading and not peg the meter full scale or any ALC indication very far past the black border. If that is not how you left this step then this is likely your problem.

6. As an experiment. Record the setting of VR-7. Flip to Send with Processor off. When meter pegs hard right reduce mic gain slightly to just get if off the peg. Then slowly tweak trim pot VR-7 (on IF board at base of Q31). You should be able to move meter indication down to the ALC box max border or S9.

7. If you can move ALC reading down then go ahead and repeat Step 31 before returning to Step 32. Make sure Step 31 is as accurate as you ca.

8. If you cannot adjust ALC indication down with trim pot VR-7 then there is likely something wrong with ALC meter driver Q30 and Q31 or with Q19 and Q20 on the AF board.

Good Luck-Terry K9TW

hi Craig,

these inverters output a modified sine wave.

http://www.whistlergroup.com/inverter-text2.html

any chance you can find or borrow a full sine wave
ups such as APC SmartUPS, Liebert, Eaton, etc.

I run a Liebert full sine wave ups, removed from
service at point of sale registers years ago.
To keep the ups happy I also use a TrippLite
line conditioner at field day.

you can find them on ebay inexpensive used.

I'm unsure that your proposed batteries will be enough to operate the radio for very long.

The rig/inverter combination could well pull 30 amps from the battery during transmit, and with the Ah you have suggested you may have just a couple of hours 'key down' time.

Can you run a small and dirty generator at the event simply to run a battery charger to assist the battery capacity? A charger won't keep up with the TX load, but will gain some ground during RX if the charger is of a decent capacity.

Terry, that made very interesting reading and I have saved the page to my HDD for further reference. His technical arguments make a lot of sense and he was thorough enough to highlight potential issues.

Thanks for pointing it out to me - I must confess I found myself wondering about applying the mod myself, as it is relatively simple to do. :)

Linearity of an amplifier depends on 2 things

1. The amplifier class
2. Driver stage signal level

All of the final amplifiers in the Kenwood hybrids operate in Class AB1 just like many other tube type transceivers or hybrid transceivers.

If the driver stage signal level causes the grids of the final tubes to swing positive, grid current flows in the final tubes and power is consumed in the final amplifier's grid circuit. This results in the final amplifier's output signal containing distortion and the final amplifier is no longer operating in its linear state. A regulated screen supply cannot prevent this from happening.

An additional item that determines amplifier linearity is

3. Bias voltage setting.

The amplifier's bias is set so the amplifier tube(s) operate over their characteristic linear curve. See tube manuals for more details on how the characteristic linear curve affects how a tube's output signal will be based on the bias voltage setting.

If at anytime the bias voltage is incorrectly set, either too negative or much less negative, these 2 bias settings can result in the amplifier tube(s) operating outside of the tubes characteristic linear curve leading to the output sine wave signal, whether it's AF or RF, to be distorted.

None of these problems can be prevented by a regulated amplifier screen voltage.

No, but the point Terry was making is that variation in screen grid voltage will affect bias current and therefore gain, varying with the envelope. This has to contribute slightly to harmonic distortion so regulating the screen must reduce this to some degree, and reduce dissipation within the tube too, my main interest.

31943. Re: [TS-520_820_530_830] Re: Speech Processor alignment

Hi Terry,

Sorry for the delay, I was hoping to get feedback from Mike or yourself re: the voltages... Mike did respond saying that if my IP is around 150mA (which it is), then the voltages would be about right for 60-70W output.

My 830 was working "OK" originally, although the alignment was miles off.
Then I had an issue with a tube that failed in the final unit, and it caused a number of issues.. one of which was NO output etc.

I swapped the RF board as the one that came with the unit was broke in a number of areas, so I purchased one from Bob Mansker and swapped it.
To which I decided to re-align the radio.

On doing so, I noticed that the Speech Processor wouldn't align and the output was 50 -70W maximum. - It still is the same, although RX is excellent now.
It works OK and I can happily QSO on SSB (proc in or out, it's fine) and CW, but I was hoping to get the radio at 100W and factory aligned (as close as can be).
I purchased a new front fascia and it looks great.. needs to work great now :-)

Cheers
Chris

> 1. You are telling us your problem is that with 1500 hz @ 10 mv injected into mic jack,mic gain setting around No. 4(Processor OFF), in USB mode, meter in ALC position, that when you flip to send the meter pegs off scale right hand side of the meter. Is this true?
>
> 2. The expected response would be for the meter to deflect to the far end of the ALC black box scale or somewhere close either side of the Max ALC range and not peg.
>
> 3. I dont believe this has anything to do with your Processor or Comp Level setting. Comp level pot is not in the circuit when Processor is off.
>
> 4. I am suspicious of Alignment Step 31. I remember telling you that I had difficulty doing this step as written and you had not completed it yet. I suggest you go back and repeat this step.
>
> 5. In Step 31 you adjust the ALC meter Zero (trim pot VR-6) and you adjust the Maximum ALC reading (far right end of ALC black box)by adjusting trim pot VR-7. VR-6 is easy and VR-7 is a little tricky. When you complete this step you should be able to flip to send with 10 mv signal injected and get max ALC reading and not peg the meter full scale or any ALC indication very far past the black border. If that is not how you left this step then

this is likely your problem.
>
> 6. As an experiment. Record the setting of VR-7. Flip to Send with Processor off. When meter pegs hard right reduce mic gain slightly to just get if off the peg. Then slowly tweak trim pot VR-7 (on IF board at base of Q31). You should be able to move meter indication down to the ALC box max border or S9.
>
> 7. If you can move ALC reading down then go ahead and repeat Step 31 before returning to Step 32. Make sure Step 31 is as accurate as you ca.
>
> 8. If you cannot adjust ALC indication down with trim pot VR-7 then there is likely something wrong with ALC meter driver Q30 and Q31 or with Q19 and Q20 on the AF board.

31944. Re: Speech Processor alignment

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-06-19 11:31:47 UTC

Topic: 31878 Message: 31944

Hi Chris,

Based on the HV and power output levels you provided, 850VDC high voltage and 70 watts output, that equates to an IP current level of approximately 150ma. Therefore, with those levels the INPUT power in the final amplifier would be;

.150 x 850 = 127.5 watts

Since the 830 final amplifier has an efficiency rating of approximately 55%, power output would be

127.5 - 45% = 70.125 watts

the same as your 830 is producing. That tells me the HV and LV Rectifier Unit supplies are within specifications and operating as they should.

I recommend you troubleshoot the 830's transmit signal path, take level measurements and compare your findings with the 830 service manual Level Diagram on page 44.

73s
Mike
W5RKL

> >
> > 2. The expected response would be for the meter to deflect to the far end of the ALC black box scale or somewhere close either side of the Max ALC range and not peg.
> >
> > 3. I dont believe this has anything to do with your Processor or Comp Level setting. Comp level pot is not in the circuit when Processor is off.
> >
> > 4. I am suspicious of Alignment Step 31. I remember telling you that I had difficulty doing this step as written and you had not completed it yet. I suggest you go back and repeat this step.
> >
> > 5. In Step 31 you adjust the ALC meter Zero (trim pot VR-6) and you adjust the Maximum ALC reading (far right end of ALC black box)by adjusting trim pot VR-7. VR-6 is easy and VR-7 is a little tricky. When you complete this step you should be able to flip to send with 10 mv signal injected and get max ALC reading and not peg the meter full scale or any ALC indication very far past the black border. If that is not how you left this step then this is likely your problem.
> >
> > 6. As an experiment. Record the setting of VR-7. Flip to Send with Processor off. When meter pegs hard right reduce mic gain slightly to just get if off the peg. Then slowly tweak trim pot VR-7 (on IF board at base of Q31). You should be able to move meter indication down to the ALC box max border or S9.
> >
> > 7. If you can move ALC reading down then go ahead and repeat Step 31 before returning to Step 32. Make sure Step 31 is as accurate as you ca.
> >
> > 8. If you cannot adjust ALC indication down with trim pot VR-7 then there is likely something wrong with ALC meter driver Q30 and Q31 or with Q19 and Q20 on the AF board.

Mike -- I am going to have to go back to the old ARRL and Bill Orr handbooks and the tube curves because they made such a big deal about regulated screen supplies back then and built power supplies that used gas regulator tubes to provide stable screen supplies. I had old Johnson rigs that had regulated screen supplies and heavy choke input filters to stabilize the output voltage.

I have looked at Eimac, Penta, Burle, RCA and other tetrode tube app notes and they all describe the requirement for a regulated screen supply.

I thought the only reason they got away from regulated screens was a cost savings at a sacrifice of a little linearity.

I thought that the varying screen supply varied the bias point and affected where the tube was operating on the curve.

What I think you are saying is that in AB1 the only thing that can introduce IMD is overdriving the tube and I agree regulated screen supply wont prevent over driving and that is why they came up with ALC to catch the horse after it is out of the barn.

Back to the books for me.

Terry

Subject: [TS-520_820_530_830] Re: Hybrid Screen Grid Regulation

An additional item that determines amplifier linearity is

3. Bias voltage setting.

The amplifier's bias is set so the amplifier tube(s) operate over their characteristic linear curve. See tube manuals for more details on how the characteristic linear curve affects how a tube's output signal will be based on the bias voltage setting.

If at anytime the bias voltage is incorrectly set, either too negative or much less negative, these 2 bias settings can result in the amplifier tube(s) operating outside of the tubes characteristic linear curve leading to the output sine wave signal, whether it's AF or RF, to be distorted.

None of these problems can be prevented by a regulated amplifier screen voltage.

Ok I understand the history now. Would be interested if you make the suggested adjustment of VR-7. I would like to have a new pristine front panel for my spare 830 as well. Good luck-Terry

Hi Terry,

Sorry for the delay, I was hoping to get feedback from Mike or yourself re: the voltages... Mike did respond saying that if my IP is around 150mA (which it is), then the voltages would be about right for 60-70W output.

My 830 was working "OK" originally, although the alignment was miles off.
Then I had an issue with a tube that failed in the final unit, and it caused a number of issues.. one of which was NO output etc.

I swapped the RF board as the one that came with the unit was broke in a number of areas, so I purchased one from Bob Mansker and swapped it.
To which I decided to re-align the radio.

On doing so, I noticed that the Speech Processor wouldn't align and the output was 50 -70W maximum. - It still is the same, although RX is excellent now.
It works OK and I can happily QSO on SSB (proc in or out, it's fine) and CW, but I was hoping to get the radio at 100W and factory aligned (as close as can be).
I purchased a new front fascia and it looks great.. needs to work great now :-)

Cheers
Chris

Topic: 31878 Message: 31947

Hi Mike,

Thanks... will try and figure it out.

Chris

> > >
> > > 2. The expected response would be for the meter to deflect to the far end of the ALC black box scale or somewhere close either side of the Max ALC range and not peg.
> > >
> > > 3. I dont believe this has anything to do with your Processor or Comp Level setting. Comp level pot is not in the circuit when Processor is off.
> > >
> > > 4. I am suspicious of Alignment Step 31. I remember telling you that I had difficulty doing this step as written and you had not completed it yet. I suggest you go back and repeat this step.
> > >
> > > 5. In Step 31 you adjust the ALC meter Zero (trim pot VR-6) and you adjust the Maximum ALC reading (far right end of ALC black box)by adjusting trim pot VR-7. VR-6 is easy and VR-7 is a little tricky. When you complete this step you should be able to flip to send with 10 mv signal injected and get max ALC reading and not peg the meter full scale or any ALC indication very far past the black border. If that is not how you left this step then this is likely your problem.
> > >
> > > 6. As an experiment. Record the setting of VR-7. Flip to Send with Processor off. When meter pegs hard right reduce mic gain slightly to just get if off the peg. Then slowly tweak trim pot VR-7 (on IF board at base of Q31). You should be able to move meter indication down to the ALC box max border or S9.
> > >
> > > 7. If you can move ALC reading down then go ahead and repeat Step 31 before returning to Step 32. Make sure Step 31 is as accurate as you ca.
> > >
> > > 8. If you cannot adjust ALC indication down with trim pot VR-7 then there is likely something wrong with ALC meter driver Q30 and Q31 or with Q19 and Q20 on the AF board.

Hi Andy,

I don't know what you mean by "bias current". When you say "bias current" are you talking about "grid current"? If so, how does variations in screen voltage affect grid current?

> >
>
> No, but the point Terry was making is that variation in screen grid voltage will affect bias current and therefore gain, varying with the envelope. This has to contribute slightly to harmonic distortion so regulating the screen must reduce this to some degree, and reduce dissipation within the tube too, my main interest.

Terminology accident on my part - I meant quiescent plate current, a result of the level of bias voltage on the grid, therefore 'bias current'.

This will of course be affected by screen grid voltage.

I knew what I meant, the problem being few people seem able to read my mind. :)

Hi Andy,

Based on your responses, I still do not see where variations in the tube's screen voltage will produce distortion and non-linear operation. Maybe you can explain in detail how your variations in screen grid #3 voltage produces distortion and non-linear operation.

I think that is understood by stating the class of amplifier and that, in turn,
 is determined by the bias setting.

JD

_____
From: w5rkl w5rkl@...

An additional item that determines amplifier linearity is

3. Bias voltage setting.

You actually adjust the grid bias VOLTAGE pot by observing the idling PLATE CURRENT reading for a given level. , 60MA for the TS5xx siries radios.
It can be confusing, I know !

The question I posed to Andy, and anyone else for that matter, is not about setting the bias pot for a no signal 60ma but rather how and why the belief that the screen voltage causes non-linear operation in the amplifier?

Consider how many transmitters were made with this basic final design with
no problem from unregulated screen grids. THIS INCLUDES COLLINS!

Mike,

Any idea where would be a good place to start the voltage measurements?

Cheers
Chris
